Drew Diamond, VK3XU, has published a few things in this line - in his books "Radio Projects for Amateurs" now up to Vol 3. Available from TTS Systems (one that I know of..) - excellent books, can recommend them to anyone interested in home brewing.

If you want something with calibrated output, there has NEVER been a better time to get a good used one - so much high quality test gear is being sold off, as most telcos etc no longer maintain expensive gear and trained staff to run it - cheaper to replace the equipment with a new one.

Its pretty hard to make recommendations without knowing, besides your driven element conductor and proposed feedline, what other conducting elements are nearby (housewiring, power lines, metal fences, metal plumbing, etc.). The simplest and fastest approach would be to hook up whatever you have, match it with an antenna tuner to your rig, and get on the air and see if you can make contacts and ask what your signal report is. Usually, if you can hear stations and the S meter is somewhere in the middle of the scale, then they should hear you. You can tweak, adjust, improve from that point on (and assess your TVI, BCI, and other interference problems, too).

Aside from the resistivity of the epoxy, the largest problem I see
is throughput. That is, where are you going to store all those
boards while the epoxy is curing?

Plus, it makes it really messy for the salvagers/recyclers.

Not really. Consider the angle of serviceability. It's easy enough
to use a 'HoTweezer' station to replace a bad chip component secured
with solder. It's darn near impossible to replace the same component if
secured with Epoxy.

Also, I'm not convinced that "conductive" Epoxy really is. I'd
want to see some real numbers on resistance per cm/squared on the stuff
before I even consider it for any sort of repair work.

Any job worth doing is worth doing right. If you're trying to
attach surface-mount components, invest in the proper
soldering/desoldering equipment instead of looking for impractical
shortcuts. It may cost more at the get-go, but it'll cost a lot less in
the long run.

Keep the peace(es).

I do not know about Masterbonds conductive epoxy(ies), but i have
used silver conductive epoxy.
1) EXPENSIVE, 2) good for short-term and medium-term repair, but no
where as reliable as a solder connection.

The silver conductive epoxy is extremely conductive, and even tho i
never measuresd the resistivity, i would wager that it is better than
copper if used properly.

Here are some examples of silver epoxies:
http://news.thomasnet.com/fullstory/460221
10^-3 ohm cm

http://www.mgchemicals.com/products/8331.html
2*10^-2 ohm cm

http://bondline.net/datasheets/2072.pdf
4*10^-4 ohm cm

http://bondline.net/datasheets/2080.pdf
5*10^-3 ohm cm

http://bondline.net/datasheets/2111.pdf
2*10^-4 ohm cm

http://bondline.net/datasheets/2120.pdf
5*10^-3 ohm cm

Copper:
http://www.lehighton.com/AppNotes/CuMetallization/cumetallization.html
1.68*10^-6 ohm cm

According to these sources, copper is about 100 to 10,000 times as
conductive as silver filled epoxy.

Sounds like a terrible idea. The surface tension of solder and the solder mask/PCB landing on the circuit board interact very nicely to make sure that a blob of solder and the part itself stays on exactly the right spot when you solder on a SMT component (either hand soldering or toaster-oven style). None of that is working to your advantage when you use epoxy.

Hand-soldering even fine-pitch (0.5mm) SMT stuff is not a big deal to do by hand with even primitive (e.g. just a weller soldering iron and a fine-tip point and some solder wick) tools. BGA's will require a toaster oven though :-).

Tim.

It is done in special circumstances, but not that often. SMT passives are available with different termination platings/coatings for such an application, but they are harder to come by. It won't work as well if you use devices with terminations intended for soldering.

The 3M conductive adhesives like the 9703 work well. Not sure how they do it but it conducts in the Z axis (thru the adhesive) but not accross the surface direction (X & Y axis). It's a pressure sensitive transfer adhesive (tape that you stick on then peel off the paper carrier leaving the adhesive behind)

X-Y axis Insulation Resistance = 3.4 x 10 to the 14th Ohms/square
Z axis Contact Resistance = 1.25 milliOhm-in2

Pretty neat stuff!

Ron H.

Just another point of reference. From:
http://www.efunda.com/materials/solders/tin_lead.cfm
Eutectic tin lead solder has a conductivity of about 1.44*10^-5 ohm cm,
or 8.5 times that of copper.

I have a roll of that. Very pricey. It contains lots of short bits
of very fine copper wire precisely aligned through the thickness of
the adhesive gel. The wires do not contact each other, so there is no
conductive path along the gel.

Definitely. Sort of the dual of enameled wire. Conducts only at
right angles to the length.

Sounds VERY interesting! I have some clients that need to mount
components that can't stand the heat of soldering. The only problem
might be "tenacity"... how much "shake, rattle and roll" can it take?

Conductive adhesives have been discussed in Advanced Packaging
magazine (IIRC, might have been another trade mag) and the main
problems preventing widespread replacement of solder are not adhesion
but high initial resistance (not suitable for the current required by
large processors etc), and worse, gradual increase in resistance over
time especially at higher temperatures and humidities due to slow
oxidation of the conductors as water vapor and oxygen diffuse through
the adhesive polymers. Not ready for prime time now, and might not be
for a long time due to the lack of candidate impermeable adhesive
polymers. Suitable now for low power apps in benign envireonments
where long life is not important.

Well this isnt a reply but extended question.
are DMJ4747 diodes from Alpha Industries and SEL DS332 Diodes from
bomac Labs the same as 1N23--they look mechanically identical and are
said to be microwave diodes. I am asking as I need them as detectors in
X Band but the seller does not know.

1N23B is a point contact silicon diode. For the ages that was the
closest thing to Shottkey and the diode for microwave. In a lot of
old hardware the newer shottkey diodes will easily replace the
1N23 series assuming no mechanical limitations.

FYI: the suffix specificied specific sorting of 1n23 for noise,
working frequency and threshold voltage.

>your location. Unfortunately, these tend to be kind of pricey.

Back in 1996, one of Novatech's early products was a small DDS board based
upon the AD9850. It was later upgraded to the AD9851 to allow higher
output frequency. We no longer build this item, but I looked in the back
stock area and found that there were hundreds of blank boards left. You
can see the schematic at: http://www.novatech-instr.com/Fun/dds6m_sch.pdf
and a photo at: http://novatech-instr.com/images/dds6mf.jpg

If you want one of these blank boards FREE, send a self-address, stamped
($0.60) envelope to:

Novatech Instruments, Inc.
attn: DDS6m board
P.O. Box 55997
Seattle, WA 98155-0997

and I'll get one out to you. The price is right and might get you
over the soldering hump. The discrete parts are 1206, 0805 and 3216.
We have a bunch of the key parts (micros, AD9851BRS, etc), but we'd
have to come up with a price for that.

Steve.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B
licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Aha....the CBer returns. Welcome back good buddy!

The following posts are by Gareth Alun Evans, aka 'Airy R Bean', aka 'Polymath':

Sep 6 1997, 8:00 am

As the result of holding a CB licence, I have recently received a consultative document about the future of CB Radio in this country, which suggests that serious consideration is being given to legalising AM and SSB on 27 Mhz.
--
72's etc

Sep 6 1998, 8:00 am

A group of us in Wiltshire have just equipped from Tandy, standard Midland 40 channel rigs. All work fairly well, range about 1/2 mile, less if in trees. Get your aerials somewhere else, the Tandy ones are too rigid and break easily. Most farmer's wholesalers have them.
New rig about ï¿½60, second hand about ï¿½20.

Don't forget your CB licence @ ï¿½15 pa.

As a radio ham, I was very sceptical at first (CB=Children's Broadcasting, etc) But once we got them, they are indispensable. With all the backchat besides the useful conversations, it makes it seem as though everybody in the convoy is in one vehicle and makes for a much more enjoyable day out.

Hi,
I am trying to design a 455KHz IF stage. I would like to use a 455KHz 7KHz
BW ceramic filter. Looking at the Murata data, they suggest that an
additional IFT is used to reduce the spurious responses.
Has anyone used such a scheme?
Does it mean connecting the IFT directly to the output of the filter?

Do I really need to worry about the spurious resonses?
Collins mechanical filters seem to have the same problem, but do these also
usually have an IFT as well?

Thanks,
John.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B

licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

Many questions have been raised by the technical and other postings made in the past by Polymouth and other - similar-sounding, probably sock-puppets - proponents of 'ham radio'. They have meant that the errors so made have had to be corrected, sometimes in a long thread, or spread over several threads, or merely involving a considerable spread in time. Should anyone require enlightenment, a Frequently Posed Responses (FPR) is appended.

New items added. This is Version V. It replaces all other Versions.

[ ] In the UK, no repeat no licence of any kind is necessary to specify, design, construct, modify, repair, own, or (under some circumstances) test an Amateur transmitter.

[ ] A pass in a current examination for a UK Amateur Licence qualifies the successful candidate for the issue of a UK Licence. Holders of the appropriate levels of licence are permitted to operate transmitting equipment that is not subject to a formal approvals procedure, and to carry out technical investigations. A qualification for a Licence, or the Licence itself, is not, repeat not, a qualification to specify, design, construct, modify, repair, or own transmitting equipment. See above.

[ ] Before sunrise on Friday, September 1st, 1939, Germany attacked Poland at 4:45am, when the Battleship "Schleswig-Holstein", on a so-called goodwill visit, opened fire on the Polish naval depot and garrison at Westeplatte. World War II had begun. An hour later, first German units crossed the Polish border. Britain entered the war two days later. She did not repeat not start WWII.

[ ] Because the 'dimensions' of both sides of the Radar Range Equation need a term having the units of square metres in order to

balance, references to ratios of these terms expressed in terms of decibels does not repeat not imply that they are in themselves a ratio of powers.

[ ] FM can be demodulated by an AM receiver using the 'Slope Detection' method. Placing an NBFM signal entirely within a channel in a channelised AM receiver is not repeat not Slope Detection.

[ ] A company's Returns Policy is not repeat not an admission that it deliberately produces shoddy goods, no matter how well wrapped at the time of purchase.

[ ] An IP Address in the headers of one's posts is not repeat not Secret Information.

[ ] An exemplary driver is not repeat not one who makes an obscene gesture to show that the other driver is an idiot.

[ ] An exemplary driver is not repeat not one who repeats an obscene gesture to confirm that the other driver is an idiot.

[ ] XRC is not repeat not a suitable method of differentiating between the 80 percent of metals that have FCC crystal structure.

[ ] Millimetre-waves are not repeat not generated by 'nuclear emissions'.

Depends on how much rejection you want/need to have away from the
passband. Those little 455 kHz ceramic filters inherently have "flyback"
or spurious responses in the region 100~200 kHz above the passband,
IIRC. The attenuation at those peaks may be as little as ~15 dB. So it
is common to have more than one such filter in the IF to achieve the
desired overall selectivity and IF image rejection. Usually cascaded
filters/IFTs are separated by an amplifier stage to set the correct
termination impedance for each filter. Please tell us more about the
application and maybe we can assist further.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence

Greetings One and All,

I am considering the EMTECH single band QRP kits, especially the
40 and 15 meter kits, with perhaps the 30m too.

Was wondering...

(1) Are there any kind of "users" groups for the rigs?

(2) Do the rigs have any popular "mods" published?

Direct replies to k4yz@aol.com would be appreciated, but will
check back here also.

73 es TNX in advance

Hi Steve,

I got frustrated with their site (dial up here). All I could find was the boards for the rigs at $80 each. They show them in a cabinet, but darned if I could find the cabinets.
Anyway, I would really consider the Elecraft K-1 or KX-1 kits as an alternative with lots more features/perfomance than these rigs.

Source record: 16807

Hi,
I have bought a 45MHz crystal filter with a bandwidth of +/-10KHz,
according to the spec.
Now does this mean a real bandwidth of 20KHz?

If so when a receiver states a bandwidth of 7KHz, is that +/-7KHz, ie
14KHz?

If I am designing a good communications receiver from 6KHz-30MHz to receive
AM, SSB and CW and want 2 good filters, what are the bandwidths I should
consider?

Thanks,
John.

Hey Dale....

I e-mailed them some time ago and they said they weren't going to
market the cabinets any longer...You'd think they could at least change
the site to day so, eh?

And in researching it a bit more, I see they once offered that
add-in AF filter, but now only make reference to it as a "Handbook"
project.

I was leaning to the EMTECH kits from reviews I read in HAMBREW in
the 90's (96? 97?) It's on the website too... But in any case, I
liked the appearance of the rig and the extra power was nice too...

I'd love the Elecraft kits myself too...especially the K2, however
justifying the almost $400 expenditure to Mrs K4YZ would be a bit
problematic!

Hi Steve,

Current pricing on the K1 is $289 for the 2 band rig and $359 for the 4
bander. I have built the K2 7 or 8 years back- worked right off and a
fabulous rig. You won't be disappointed with a K1.
The Sierra is also a contender- but can get pricey.
Another great radio is the Dave Benson's Small Wonder Labs line:
http://www.eham.net/reviews/detail/187
Talented designer and great support.

Likely the case. Some spec total bandwidth other specify 6db edge
as distance from the filter center frequency.

>If so when a receiver states a bandwidth of 7KHz, is that +/-7KHz, ie
>14KHz?

If they didn't put the +/- there then its 7khz total.

>If I am designing a good communications receiver from 6KHz-30MHz to receive
>AM, SSB and CW and want 2 good filters, what are the bandwidths I should
>consider?

AM wide 12-16khz
Am narrow 6-10khz

SSB anywhere from 2-3khz with many around 2.4khz wide Any wider
than 3khz will be poor in crowded bands. I happen to prefer 2.1 to
2.3khz.

CW I've seen 1.4khz all the way down to 200hz most consider
400-600hz adaquate.

In all cases the skirt selectivity usually bandwitdth measured from
the 6 to 60db points are important indicators of filter quality and
any value of 2 or less is good enough and 1.4 would be excellent.
The idea is you'd ike to be able to put the offending signal outside
the bandpass and well attenuated.

What some builders do for CW is use the CW filter and use an peaked
audio filter to narrow the audio band pass. Not quite as effective
but often cheaper.

Allison's advice is right on the mark.
I recently built an amateur only band HF receiver and chose 6/2.5/0.5 for the three modes.
I think what Allison meant to say about the peaked audio filter was to use it in conjunction with the SSB filter for CW selectivity.

That 45mhz would make a good 'roofing' filter to use ahead of a 455khz if filter. Normally using a first if of 45mhz and a second if of 455khz would result in 'second order' images leaking in, but with a good roofing filter ahead of the second mixer the problem is solved.

Some years ago, I bought a bunch of 9mhz if filters at the Dayton Hamvention. They are 3.2khz BW (at the 6db points) filters made by CF Networks for the Gonset Sidewinder transciever. I think this was a vhf rig, which would account for the wider bandwidth. However, these are 8 pole filters, with a shape factor of 1.08 @ 15db down (rises to 1.23 @ 45db down). With this shape factor, these filters probably have similar rejection of off frequency qrm as would a 2.4khz filter with a 2.0 shape factor. Since I have a bunch of them, I could use 2 or even 3 of them in the IF stage (one after the mixer, one before the detector, and one between stages). This would decrease the apparent shape factor even more. The nominal carier frequencies for these filters were 8998.0 khz and 9001.7 khz. With the 3.2khz bandwidth this put the cariers 250hz outside the stated bandwidth (-15db point for these filters).

I wonder just how these filters would actually work out in a rig today. That 3.2khz bandwidth DOES seem a bit wide, but the crazy shape factor seems to make it worthwhile to try.

4530. Wanted: KAM All-Mode EPROM

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-11 04:10:40 UTC

I recently was given an older KAM All-Mode TNC. It only has version 3.06 firmware. I was hoping to find a version 5 or later EPROM. Does anyone have an EPROM to sell me or can tell me where to get the bin file to burn my own EPROM. I have talked to Kantronics and they told me they no longer support this TNC. Thanks.

Bill

4531. Re: Receiver bandwidth .. dayton filter find!

Source record: 16814

For VHF 3.2 would likely work well enough except if there is a
sporatic E opening and people tend to pile up. Then it's really wide!

For filters I use microprocessor crystals in the ladder configuration.
With the correct shunt C and 4-8 crystals you can make a very fine
crystal filter with bandwisths from 2-400hz to as wide as you may
want. The design process is documented elsewhere (see EMRFD
and the handbook as well as internet). I build for 6 and 2m and have
built very nice ladder filters this way. Also since microprocessor
crystals in the range of 4-20mhz are dirt cheap it's also a help.
Also the higher the frequency the less likely dual conversion is
required to avoid images and allows the selectivity to be closer
to the antenna (better overload performance).

My latest 6m rig uses 12mhz crystals, 8 of them for a 2.3khz
bandwidth at 6db and 3.9khz at 60db with symetrical skirts.

Maybe it's my aging male ears but I've never heard an AM transmission where a >10kHz filter was needed or even desirable. Whenever I switch on the wider filter I just hear more hiss and static, and no more fidelity.

I can hear a small difference between 6kHz, 8kHz, and 10kHz with local AM BCB stations. My preference has always been to abhor hiss so I tend to go towards the narrower side. I don't think my ears are as sensitive to hiss as when I was younger but it still bothers me especially with extended listening.

I am told that the 16kc wide filter on my R-390A was used largely for when multiple channels were being multiplexed (e.g. multi-RTTY or multi-voice channels).

Tim.

In my homebrew receiver (see QRZ.COM), for SSB reception using headphones, I toggle-switch in a modified audio response increase in the upper range of speech frequencies, 3 dB at 3000 Hz. This greatly improves speech intelligibility at low audio volume, and this saves my aging ears from overload, especially when listening to weak signals. It is important to protect hearing, at any age.

That is because most AM broadcast station use brick wall filters at
around 4-5khz. Use to be a time back in the analog days the roll off
was both higher and gentler. Of course the Beach Boys surf music
was current then.

I also listed two AM filters for that reason. Completeness only.
Though some of the 75M AM window folks (3885khz) insist that
a wide filter is useful.

>I am told that the 16kc wide filter on my R-390A was used largely for

That may be but AM used ot be much better fidelity at one time.

Hi,
Im confused regarding the choice of iron powder toroid for a 7Mhz high pass filter. I need to use a small size (T68) toroid. For the freq range, some reference texts say T68-2 is the one, others say T68-6" grade. I see differing "best Q range" specs for the 6 grade.....2-30Mhz......10-50Mhz...etc.
Have similar need for 20Mhz LPF, but assume "6" is really the choice there.
Any suggestions as to the relative differences and reasons to choose between grades 2 and 6 for the HPF in T68 size?
Thanks,
JEFF

As far as I know, 7MHz is on the border between using one mix or the
other. You'll see different Q's because details of winding, wire choice
and mounting will affect Q, as would use of a core from another
manufacturer (I don't know if anyone other than MicroMetals uses that
system, but if they did I wouldn't count on it being standardized).

If you're not going to be hitting it with really high power and if you
don't need it to be highly resonant I wouldn't worry too much. If
you're going for an engineered solution then you should make a number of
"identical" coils and test them; just make sure that the coils you make
are representative of what you'll be manufacturing.

Either grade 2 or 6 should work fine at 7 and 14 MHz. The Al values
differ somewhat, so the number of turns to get a given inductance will
be a little higher for grade 6 than grade 2. You only need to confirm
that the number of turns required will actually fit on your T68-size
core.

For a given number of turns, the unloaded Q does peak at one frequency
but is still quite good on either side of that frequency. Unless you
have some real need to achieve the highest possible Q for a given
inductance at the frequency of interest, I wouldn't worry too much about
it. Wind the toroids, build the filter, and see how it works out!

Having just been playing with Micrometals cores myself, I gather that -2 is indeed the 'best' for higher frequencies.

The local distributor says it's stocked in greater depth too.

Have you also looked at Magnetics Inc and Arnold ?

Not that this is an exact science but typically I switch from #2 to #6
around 10MHz. But I never design with high Q because that can be a pain
in production.

John, if you really want to listen to CW and FSK signals in the VLF
band (8-30 kHz) then you will find a 100 Hz filter very useful.

>when multiple channels were being multiplexed (e.g. multi-RTTY or
>multi-voice channels).

As a point of historical reference, the "390" series was intended for fixed-point to fixed-point communications reception as well as in the land-forces' AN/GRC-26 truck-mobile HF hut. The wide bandwidth was intended to be used with "commercial-government" SSB that had a 12 KHz wide bandwidth to accomodate four 3 KHz "voice grade" channels frequency multiplexed. Each voice channel could handle 4 to 8 TTY circuits, each using tone-pairs (one for Mark, another for Space) via auxilliary "carrier" equipment. A common arrangement was to have one voice channel as the "order wire" or command channel, a second voice channel as an "overseas radiotelephone" circuit, the remaining two voice channels used for TTY circuits. Depending on the carrier and auxilliary equipment, TTY tone pairs could be doubled to take care of selective fading effects common on HF long paths.

For some illustration of actual use of R-390s at a large receiver site, go to http://kauko.hallikainen.org/history/equipment and look down the page at "stations." Click on the 1962 communications station link for a repro of a booklet produced by the Japan Signal Service Battalion about Army station ADA in Tokyo. ADA shared the receiver site with the USAF and the antenna field was over dozens of acres of small farms northwest of Tokyo. PDF is about 10 MB.
I was assigned to the transmitter and control sites at ADA.

The "commercial" 12 KHz wide SSB was standard practice on HF from the 1930s. Not many left in service now although there are a few unmistakable continuous-roaring-multi-tone commercial SSB signals to be heard outside of ham bands. The "roaring" sound comes from the TTY tone pairs (at least 8 circuits per station).

Thanks for all the suggestions. Ive got some Amidon T68-6 toroids to wind up, and will test the completed filter on a spectrum analyser next week.

4549. Pulsing LEDs for higher efficiency

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-12 23:28:03 UTC
From: Tom Coates <tecoatesHatesSpam@comcast.net>
Message-ID: <2-idnQXJaNeGAdDeRVn-rg@comcast.com>
Source record: 16832

I want to build some emergency lighting equipment using LEDs and 12V. A friend told me that it is possible to get more light per Watt by pulsing the LED to instantaneous levels well above its average ratings.

Is this true, if you include power consumed in the pulsing circuit?

If it is, can anyone suggest a simple and cheap circuit and the appropriate operating values?

The reason for the 12V requirement is that I'm also working on a solar charger for my transceiver batteries and want to use the same charger for the lighting batteries.

Suggestions would be appreciated.

Been there, done that. In the practical case, what you can expect
is a very slight change in insertion loss in the passband, perhaps
a less sharp transition of attenuation at cutoff, depending on the
type of highpass. It can be modeled in any SPICE analysis program
with accuracy if you make a special model that adds a series R
element computed from reactance divided by Q.

For a highpass filter, the usual filter type has the inductor in
shunt. In that configuration the inductor has a reactance
directly proportional to frequency and will have little effect on
the insertion loss in the passband. The equivalent series R due to
Q won't matter much at 1/3 to 1/4 the cutoff frequency. It might
matter on attenuation in the stopband region but the analysis on
that is more difficult and a practical build-and-measure is the
quicker way to go.

For a lowpass filter, the usual configuration has inductors in
series and there the Q of the inductors will affect insertion loss
more. Those would use the lower frequency range for powder mix.

In a highpass filter it is important that the capacitors have a
minimum series inductance so that the 5x to 10x cutoff frequency
isn't disturbed. Since capacitors are usually in series, their
Q will effect the insertion loss. Fortunately, most capacitors
will have a good Q up around 500+ and won't be a factor.

Use what you have and measure the results (you've got a spectrum
analyzer handy so that's taken care of).

I made a fairly good, practical Synthesis-Analysis program for
L-C filters that includes automatic modeling of (separately) all
capacitor Qs and inductor Qs. I can attach that to private mail
if you want it. Freeware. Proven by practical test comparison.

This pulsed drive technique is supposed to take advantage of the human
vision's persistance. If the led is driven brighter for a long enough
time the eye will perceive it as being brighter than if using the
equivalent average continuous current. Visual persistance is
approximately 10 milli-seconds, and if the repetition rate is faster
than this then the led will seem to be on all the time. The same
technique is used with multiplexed digital displays.

One problem with pulsed led drive is that it generates rfi due to the
rapidly switching voltage levels. Unless care is taken with risetime,
wire lengths, decoupling, and shielding, then the gain in efficiency
is a doubtful tradeoff for the simplicity of direct dc drive. It
depends on the application. If you want really bright flashes then use
a xenon strobe tube.

RFI isn't going to be a problem if the switch is close to the application.
You can use an LM3524, NE555 etc. to drive the gate of a MOSFET.

The tradeoff is between LED life and pulse current. See www.agilent.com for
pulsed LED application notes.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B

licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

As I understand it, this is not true --- it was true in a way for older
LEDs, but isn't true for modern LEDs. Pulsing a diode above its rated
current could get it to emit some of its light at shorter wavelengths, which
were closer to the middle of the visible spectrum and so seemed brighter.

But if you're not taking advantage of that effect, then I don't
think pulsing gets you anything. The instantaneous output of the LED is
proportional to the instantaneous current, and the percieved brightness
of the pulsed light source is the same as the average brightness, if it's
pulsing fast enough (> 10 Hz or so). So it works out that the percieved
brightness is the same as it would be if you'd driven the LEDs with
a constant current.

If resistive losses are significant, then pulsing will actually reduce the
overall efficiency, since resistive losses are proportional to the
average of I^2.

On the other hand, if your battery is at a higher voltage than you want
to drive the LEDs, then pulsing them might be more efficient than using
a linear regulator --- that has more to do with the inefficiency of the
linear regulator than anything to do with the LEDs, though :-)

I did some googling to refresh my memory about pulsed LEDs and found
a short article on the subject:
http://www.caves.org.uk/led/foot4.pdf

On the other hand, I also found some articles on pulsed LEDs saying
the opposite --- that the percieved brightness of a pulsed source
is closer to the peak brightness than to the average brightness.
It might be worthwhile tracking down some actual experimental data,
or doing an experiment yourself...

From: Dave Bullock <DaveB@ihr.mrc.ac.uk>
Message-ID: <dinkhlptq2@oyez.ccc.nottingham.ac.uk>
Source record: 16841

Has anyone got a copy of (or know where to download) a service
handbook/schematic for the Standard C110 2m handie.
Alternatively has anyone encountered a fault where it transmits &
receives, 10MHz above the indicated frequency on the thumbwheels?
I would imagine there's a down mixer and the synth is not running at
signal frequency for this age of rig?
Are there jumpers/links inside that someone might have messed up as it
will still transmit (out of band) with this fault?
Please help.....thanks in anticipation...
Dave

If the brightness of an LED is a 1:1 linear relationship with the power supplied, that suggests that perceived brightness of a pulsed LED would be neither at the arithmetic mean (average) nor at the peak but rather at rms (root mean square). Comments?

4559. High Voltage Caps for Plate Supply ??

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-14 07:08:21 UTC
From: Rick Frazier <rickf@rickfrazier.com>
Message-ID: <434F598A.C6C9F482@rickfrazier.com>
Source record: 16840

I have an Ameritron AL-1200 amplifier, and it came (used) with a capacitor problem. Upon inspection, 4 of the caps and 3 of the resistors in the Plate supply have been replaced, and some of the caps are in pretty sad shape (not to mention half of them are 220uf and the other half 270uf...).

Upon a closer examination of the unit and schematics, I find the plate voltage is expected to be at 3600 volts (more or less), the manual has a warning about avoiding transformer taps that produce over 3700 volts, and the total of the capacitor bank rating is 3600 volts. (8 caps in series, 450volt rating. Each cap is 220 uf, so the entire pack is 3600 volts, 26.25 uf)

I was in high tech engineering (computers and peripherals) for 20 years, and we never ran electrolytics at anywhere near their rated voltage. Permissible margins for low voltage DC circuits were 50% or more margin. Typical rule of thumb was 100% margin (a 10 volt cap running on nominal 5 volt line, etc.). Even in an industry where every penny of component cost was significant, submitting a design with electrolytics running with as little 25% margin typically got a less than stellar response during design reviews, to say the least.

So, I was very surprised to find the capacitor bank in the AL-1200 running at or slightly above the rating of the capacitors. It just looks like a problem waiting to happen to me. Judging by the components replaced by a previous owner, I think that at least some of the capacitors failed in the past, possibly catastrophically... As I wish to prevent (or at least reduce the likelihood of) this happening in the future, I'm looking for capacitors that can replace the existing ones with higher voltage units. Unfortunately, there just aren't many manufacturers that have 500 volt electrolytics in their product line, and probably few stocking distributors that would have any in stock (or order them for a small order quantity).

The part numbers I have found that will work for me (in order of preference) are listed here:

Cornell Dubilier (CDE)
520C271T500AB2B 270uf 500 volts
500C311T500AB2B 31o uf 500 volts
520C341T500AJ2B
550C361T500AJ2B
500C381T500AJ2B
520C401T500AC2B
DCMC321T500AB2B
DCMC401T500AJ2B

ALS30/40 series BHC Aerovox
ALS334H331D3L500
ALS30A331DE500

All of these are "computer grade" with screw terminals, and range from inverter duty down (in order, from the best are 550C, 520C, 500C, DCMC).

Do you know of any distributor that currently stocks these? Price would be good too...

I need 10 of any one part number. I am in process on gathering supplies to make my own PCB to use 10 caps (instead of 8) so if I can get the 500 volt capacitors, the rated capacitor bank will be 5000 volts and 27 to 39 uf, which should provide a decent margin for a 3600 volt supply (and not blow up if my line voltage rises and I see 3900 volts, which happened to me at a former QTH). There's _just_ enough room for the larger PCB for the 10 caps (and resistors) in place of the existing board with 8 of each.

I know where to get CDE DCMC271T450AA2B (450 volt, 270uf) which would give me a 4500 volt 27uf pack, but really would prefer to have the extra margin of the 500 volt capacitors. I can wait a bit for reasonable lead times, as the amplifier doesn't need to be in operation next week, but I don't want to still be looking 3 or 4 months from now.

I'd appreciate any leads to suppliers of any of the above capacitors (or their equivalents). I can't say that price is no object, or I'd just buy a big QRO amp and sit back, but that's not the way I do things... I should expect these caps are going to be somewhere north of $20 each, even at Qty 10.

Thanks

RF> Thanks
RF> --Rick AH7H

Rick, it is okay to run electro's at about 80% of their voltage spec.
Electro's are formed at up to 140% of their final spec and can thus
tolerate turn on surges. It is the turn-on surge spec that one should
worry about because that is when the electro is vulnerable. At turn on
an electro re-forms a little bit which draws a larger current than
usual. If that current doesn't fall off rapidly enough the electro can
become damaged and leak permanently. In the old days electros used to
be stamped with both surge and working voltage ratings.

Isn't using an electro at 50% of spec rather conserative? I might
understand being this prudent with semiconductors. An electro also has
a leakage current spec at the rated working voltage. There isn't a
direct linear relation between voltage and leakage. The relation is
more like a reverse exponential and the leakage current drops off a
lot more at a lower percent of rated voltage.

RC> LED would be neither at the arithmetic mean (average) nor at the peak
RC> but rather at rms (root mean square). Comments?

I'm pretty certain it is not a simple rms function because the
duration of the visual persistance effect must be taken into account.
If the peak brightness duration is long enough it will be perceived as
brighter than the average. Consider that the eye's retina cone signal
fades off say to 80% in 10 milliseconds after exposure to light. As
long as the light pulse repetition rate is high enough such that it
results in a drop of optic nerve signal less than the minimum light
change that can be perceived then the light will be seen as
continuously bright. You can always run a subjective experiment on
your workbench with an led and a 555 timer used as an astable.

Perhaps. But, will it _illuminate_ any better?
The OP wasn't interested in _staring_ at a bank of leds. :-)

Maybe better discussed in rec.bio-tronics HI!HI!

About 10 years ago there was considerable attention to this is the press. We looked into it and didn't find anything which looked promising and neither did the industry. For non critical circuitry, I suspect there is possibilities

My idea (which was chuckeled at) was " conductive Velcro" Make parts with the loops and boards with the hooks. Easy repair, eh? Zip off the old, stuff on the new... No heat, no time to cure...

Imagine a demo of this compared to solder in the early days...

Let's look at the options for electronics assembly. Well you have two choices:
1- Dip everything in molten lead.
2- stuff 'n go.

Which do you pick...Hmmm difficult chioce, eh?

Ther ewas also something called "particle interface". Many small sharp conductive points on the PCB, but how to anchor the parts. This was intended for test fixtures.

While I understand the Persistance comment, I don't think this is it. A couple of things. The eye has to convert the light energy to chemical reaction/change and this takes energy. The perception, therefore, would also be a factor of energy and a short pulse has less energy than a long pulse, so this would bring you back into the average vs, RMS discussion and favor the RMS idea. In other words, One would think power is what is being received, just like our ears, so the RMS idea seems to have merrit. However, I recall reading that the eye is a "somewhat" peak detecting device (my paraphrasing of part peak / part RMS) and that was the reason (or part of the reason) that the pulsed LEDs looked brighter.

BTW, shining the LED onto a surface would have the same argument, so "_staring_ at a bank of leds" isn't a factor.

I managed to buy over 400 pcs of 8.3886mhz crystals on ebay, for
just pennies each. I am planning on trying to build ladder filters
with them. These crystals are in the larger HC6/u size holders which
are supposed to work better than the miniature size used in the micro-
processor crystals.

First step would be to build the DDS vfo for
the radio since I can program the DDS to function as a sweep generator
for aligning the filter. With the DDS sweeping the output frequency
while providing a sawtooth ramp to drive the scope sweep in step
with the frequency sweep I could see the actual bandwith plotted on
the scope.

The HC6 parts work fine as do the HC18, 49 and so on. The real trick
is doing the work to measure and check the crystals for use and then
calculate the capacitors and termination impedence based on that.
For a little work you get fine filters dirt cheap.

While I have a DDS to do that with I found that using the first "high"
crystal in a VXO that gets calibrated worked as well with a lot less
fuss. Then I can use the same osc to sweep the filter later to test
it by adding a varicap doide.

That would work fine, but with the DDS, I can program the actual
frequency range to be swept and probably be able to calibrate the
scope face to read the actual frequency 'break' points on the filter.
Using the vxo method will get you a working filter quickly no
doubt, but I will still need the DDS vfo for the finished rig, so
I just figured I'd do that first.

How many 'rocks' did you use in an SSB filter? I've seen some designs on the web with 6 crystals, would the shape factor be any better with 8 or more? (with over 400 crystals in the junk box I can go crazy, but I'd still have to find the capacitors :-).

Just sweeping a filter designed for SSB would be fine I suppose. I recently
had an opportunity to hear the difference between a stock FT-1000 CW filter
and one homebrewed with attention paid to group delay- the difference was
very clear to hear- in favor of the homebrew filter.

Makes sense. I found the other way easy when DDS chips were 55$ each!
The varicap sweep is calabrated to the scope so that was not an issue
for sweeping the filter. I found that using wideband noise and a
sound card was better.

I'd say 4 is a useable minimum. With that I'll add the skirts at 40db
down are not very good though. I've used 6-8 to get a good 6-60db
shape (under 2:1). There is a problem if you go for too many. The
filter can have enough group delay that while it's shape is good, the
sound has a hollowness.

The caps, once you figured the qalues you will likely end up using
parallel values. IE: 232pf may be a 220+12pf or a 220 and a 4-20pf
trimmer.

Allison

My prefered filter has a gausian to 6db shape for less ringing and
group delay. I work for that goal.

However, try the KK7B Phasing rigs for sound. They are direct
conversion SSB (image rejecting) so all the selectivity is in the
audio bandpass. I use a miniR2 and T2 pair on 6m and filter
artifacts like group delay aren't there. Transparentcy is a good
word to describe it.

Source record: 16862

Asimov and Steve:

I would agree, designs for lower voltage operations (at 50% of spec) tend to be much more conservative, particularly when the actual cost differential isn't that great, but it really does seem to cut down the failure rate. Also agree on the 80% figure, and that's what I'm trying to achieve (at minimum) with the change to higher voltage caps, (and relayout of the pcb to use 10 caps). Even if I can't get the higher voltage 500V caps, I can still get nearly 20% margin at the nominal 3600volt DC level, leaving some extra capacity for an occasional surge... I remember testing 50 caps at a time in my "blast box" to see how long they would withstand their surge rating. Yep, more than a few disintegrated during the testing, and many bulged without actually coming apart, all within as little as a few hours at the rated surge voltage. If I remember correctly, I also saw about a 5% failure rating at rated voltage within a few hundred hours, though the particular units tested at that time weren't computer grade or inverter grade caps like the part numbers I'm currently looking for. Of course, testing with a higher ripple content always broke the caps down faster than nearly pure DC, but you'd expect that just from the heating effect of the ripple current alone. Sometimes I don't even want to think about the hours that were dedicated to finding caps with both a low leakage figure that had a decent margin, and a long life so they could be used on part of a product that spent about a third of it's time on (lithium) battery power.

Most caps are no longer marked for surge, but the datasheets typically show the surge rating. Unfortunately, you have to be very careful with surge figures, because some manufacturers seem to provide "absolute maximum" ratings instead of safe "momentary" surge ratings. Of course, it's up to the purchaser to determine whether the published ratings are satisfactory for the intended use (as I was quoted on many an occasion when inquiring of the manufacturer in years past. Just try to get a manufacturer to state in writing what they mean by "momentary"...

Having performed "accelerated aging" tests to help determine the failure rate of stressed components, and compared it to actual field failures, I know that it isn't an exact science by any means. At least this is only a capacitor. Just try to get decent information on a battery (numerous experiments with lithium thionyl chloride types comes immediately to mind...) is like searching for chickens with teeth. If capacitor manufacturers treat their products like some battery manufacturers did 10 years ago, it's a wonder they even stamp a rating on them... Of course, a tolerance rating of -10%, +50% on a capacitor should be a telling item to begin with...
[sigh]

Thanks for the response.

What is Ham Radio?

(Nothing whatsoever to do with Leigh Preece M5GWH
and his infantile Childish Broadcasts (CB), that's
for sure!)

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of Radio Hams but who are in reality nothing more than an apology for the failure of a CBer are those class B licensees who falsely proclaimed that they were against the use of a Morse Test to control access to the HF bands, until, that is, a test was introduced at their intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to enable them to handle even the simplest algebraic manipulation for Ohm's Law and thus, the disgraceful Class Ber's in the aforementioned category are not Radio Hams by any stretch of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds, or has ever held, a licence issued under the gangrenous degeneration that is the M3/CB Fools' Licence scheme!

I notice in the new 2006 MFJ catalog there is listed several roller inductors, turns counter and crank, among various sundry parts for homebrewing. Their prices seem to be most resonable....wonder how good their quality?
I am looking to procure a roller inductor, turns counter plus crank for a homebrew ant tuner.

4585. Re: Receiver bandwidth .. dayton filter find!

Newsgroup: rec.radio.amateur.homebrew

Message-ID: <6J84f.437250$x96.418250@attbi_s72>
Source record: 16868

A common mistake in years past was to try to put all of the selectivity into a single super-deluxe crystal, mechanical or digital filter. These filters quite often have "raspy" noise interference at the edges of the passband (especially in CW mode) due to the enhancements of spectral noise peaks at the very sharp band edges, caused by the conversion of the phase statistics of noise to amplitude statistics (each edge of the filter acts like a phase disciminator). This raspy noise interferes with weak signals.

The filter can be equalized for group delay, as mentioned, with improvement in the problem. The band edges can be softened, with good results. A much better way is to use two or more intermediate-performance filters in cascade. This method softens the edges so that the effect is greatly reduced. It also improves overall shape factor. A cascade in this manner of identical bandpass or audio lowpass filters tends in the limit toward the Bessel or even the Gaussian response. Digital filters can also use a method called Transition Band Sampling (see Oppenheim and Schafer 1975 or Oppenheim and Willsky 1983). All of these results are related in principle to the Central Limit Theorem of statistics.

The cascaded filter approach is also very beneficial in other respects, in particular the reduction of wideband noise in high-gain IF amplifiers. This noise degrades AGC performance and adds audio frequency noise to the product detector output.

Your margin would be determined by your tolerance for failure. If
you're making 10,000 units per year, each with 10 caps in them and
want to keep your cap related failures to less than, say, 10 per year,
then you need to be a lot more conservative than if you have a single
device with 10 caps in it that you want to keep your odds for failure
under 1% per year.

For most of the items I fix around here, I like to approach the
problem in a way that I can think of the solution as permanent, but
when you have a sample of just one, a 1% annual failure rate is about
as close to perfect as you'll ever get,

I'd say that for 450V caps, you're being much too conservative. We
have banks of 450V caps at work, each bank with about 200 caps in it.
They are used for energy storage and charged slowly and discharged
rapidly about every 5 minutes all day long. We have about 10 such
banks. We have occasional failures, maybe 1 cap every 3-4 years. We
don't think that's too bad.

I'm currently working on some upgrade banks which will have about 90
16,000 uF, 450V caps per bank. These will be run at 450V, and we'll
have 16 such banks in the second phase of the project. United
Chemi-Con doesn't seem to have any problem with this. We expect
occasional failures, but we also realize that anything else is just
being unrealistic.

C-D lists computer grade caps rated at 500 and 550 V, each with surge
ratings higher than that. United C-C does, too, but they admit that
their etched alum foil for those voltages is not as advanced as at
450V, so the energy density is not as high. This does not sound like
it would be a problem for you.

Another thing we noted with interest was that the C-D catalog said
that grading resistors were not necessary when installing caps in

series for higher voltages, especially if all the caps were from the same batch.

If I were you, I would just buy the caps you need/want at 450V, and then buy a couple of spares from the same batch. You would want to reform these if you ever needed them, but they would give you the necessary assurance that you'd be set for life.

Polymathazine (Eggy 2,4-Dimethyl Beanoxide) should be taken with extreme caution by patients with cardiovascular disease and high blood pressure. Polymathazine is a potent psychobabble agent and increased pulse rate and transient hypotension have both been reported in some patients exposed to this toxic and irritating substance. Use Polymathazine cautiously in patients with a history of seizures since the substance tends to lower the seizure threshold and frequently leads to the red mist. In general, Polymathazine does not produce psychic dependence; however, gastritis, extreme nausea and vomiting, dizziness, and tremulousness have been reported. CHECK WITH YOUR DOCTOR AS SOON AS POSSIBLE if you experience changes in vision; Tourettes fucking syndrome, changes in breasts and nips; changes in menstrual cycle or moped; deep throat; hysterical laughing, genital rash, muscle spasms of face, neck, or arse; difficulty swallowing his crap; spunk gurning and bubbling; mask-like face; tremors of hands; restlessness; tension in legs or weakness of arms or legs; sonic diarrhoea and frequent nightmares.

Jim:

Thanks for the response.

Wow, with cap banks like you describe, there's some significant energy there... What are you working on, a pulsed cyclotron?

Let's see, given your 10 banks with 200 caps each, that's 2000 caps and only 1 failure every three years, your failure rate is nearly insignificant. With a failure rate that low and a cycle rate you described, I'm supposing you are charging them with nearly pure DC, but without knowing the application, it's hard to guess... Of course, 200 caps in parallel mean leakage of about 800ma, so you've got to have a pretty good supply charging those caps.

A bank of 90 caps at 16000uf each looks like 1.4 farads. That's an incredible amount of storage at first look. The leakage alone on a bank like that would be about 400ma. To charge them slowly, I'd be interested in knowing the charge time, and what is being used to limit the charge current. Is it an active supply with a ramped current, or as simple as really high wattage limiting resistors?

In the linear amplifier, there are really a couple of things that tend to kill the caps. First, the ripple current tends to heat the caps, which are in a relatively warm location to begin with, sitting right next to a fairly large transformer, and a full wave bridge just above them. The transmitting tube is on the "other side of the wall" so to speak, but I'm sure it does contribute to some heat in the area. I haven't had this particular amplifier up and running yet, so can't instrument it to find out what the temperatures are, but I wouldn't be surprised to find it at 50C or higher, as the cooling air is all directed into the tube chimney and no particular attention has been made to cooling the capacitor bank. Given the ripple current, I wouldn't be surprised to see 80C, which is dangerously near the rated temperature rating (at least for me). Next, we have the typical cycle service an amateur amplifier puts these through, with a nearly uncontrolled charge (limited somewhat by a series resistor in the primary supply for the first second or so on an initial power up), and the demands as the amplifier is used. Now, given that the capacitor bank is never fully discharged, and the voltage across the bank is 3600 volts, the transformer rated at only 0.8 amperes, and the amount of current required during typical transmission, the heating from ripple current is probably the biggest concern for the initial design.

However, given that I live in an area with less than perfect regulation of the incoming AC line, I tend to be a bit gun-shy about what I see personally as a "marginal" design. At my last QTH, the line voltage per our local Hawaiian Electric Light Company (HELCO) should have been between 230 and 240

volts. I was the last house on the end of a 1 mile run of utility poles, and the transformer, which was over 300 feet from the building, served only my house and workshop at the time. In my workshop, I ran a single phase to 3 phase solid state inverter for a 3 horsepower wood lathe. During a period of two years, even with rather sporadic use after the first year, I had four inverters fail, and the failure was always the input diode bridge. After the first failure, I instrumented the AC line and kept graphs on it. The line voltage ranged from 235 to 243 volts over the typical 24 hour period, and tended to be around 239 volts much of the time, which I see as the nominal voltage for that location. Unfortunately, there were times when the voltage would rise to as much as 255 volts for brief periods of time (usually only a few seconds, but one prolonged instance went over 15 seconds). I didn't actually catch any high line spikes during operation of my lathe, but there were times I forgot to turn off the inverter and would come back and find it dead in the water a couple of days later. I finally eliminated the problem by putting a buck/boost transformer in the circuit, reducing the nominal voltage to 227 volts. Now there is a definite possibility the particular inverter input bridge wasn't properly rated, or wasn't up to spec, but all problems went away once I got the line voltage down (and the observed spikes at or below 243 volts).

Now thinking about the amplifier, which is supposed to produce 3600 volts with a nominal 240 volt input. Given some likelihood of seeing spikes to 255 volts, I could easily imagine the capacitor bank seeing 3825 volts for as much as 15 seconds. OK, not a long time, considering the really big picture, but looking inside the amplifier and seeing that three of the bridging resistors (50K ohm, 7 watts) and 4 of the capacitors were replaced at some time in its history, I am tending towards getting more margin into the design.

My tolerance for failure is low. I would prefer to get this amplifier up to snuff, put it into service, and never have to open the case again. I know that's a fairly high goal, but the AL-1200 uses one of the longest lived tubes in this type of service, and I'm unlikely to overdrive it so long as I load it properly, as it can withstand 130 watts and both of my transceivers only put out 100 watts..

I can purchase the 450 volt capacitors for about $10 each, so the 10pc bank will cost me about a hundred dollars. Add another $25 for new resistors and $20 for the supplies to layout the PCB for 10 caps, I'm looking at $145 to have a 4500 volt capacitor bank. If I can get the 500 volt capacitors, they will likely cost $25 to $30 each (lower volume, fewer dealers, etc.) and I would have a 5000Volt capacitor bank for $295 to $345 out of pocket. If I just replaced the caps and resistors on the original PCB, I'd be out $125, but have a 3600 volt bank. With 500 volt capacitors I'd be at 4000 volts. Given the circumstances of apparent previous failure(s) and my low tolerance for failure 'on my watch', I would feel better having the extra headroom, even with a price premium well over double. (Funny how it comes around to the warm fuzzy feelings isn't it?) Of course, f I don't find a supplier for the 500 volt capacitors fairly soon, impatience will take over and I'll end up buying the 450 volt ones anyway!

Of course, in the back of my mind (and not previously mentioned) is the possibility of running the amplifier from the 220 volt tap on the transformer, which would give me 3925 volts nominal on the bank at 240 volts, and 4010 volts on the bank at 245 volts, and 4175 if I see the same sort of 255 volt spike at the new QTH. I've done dumber things in my life and could see a possibility of it happening in a moment of weakness, so I'm also buying some insurance by going to the higher voltage capacitors and the new PCB. The biggest reason to run a higher voltage would be to allow getting full legal output with a lower drive from the transceiver. I would prefer to run with less than 100 watts out from the transceiver, but thinking about it, it would likely only be about 10% or so less drive, so perhaps it isn't worth all the work for that reason alone.

Thanks
--Rick

This Sunday.... The seasons last...

+++ Now even more Buyers Parking !!!
Thanks to TKT we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday October 16th 2005
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which
offers a 30% discount. By prepaying you get a
discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,

will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776

********** $1 buyers discount with hard copy of this notice ***********

<<<<<<<<<<<<<<<<<<<<<<< cut here >>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

Mail the coupon below by the 5th of the month to be a Prepaid Vendor.

FLEA at MIT 2005 Rates

SELLERS

To use your prepaid spaces the named vendor MUST be present.
Rates include one admission per space.

Advance $17 First space - includes $10 Cambridge Vendor License
$12 Additional Spaces
Must be received by the 5th of the month.

Gate Admission $20 First Space - includes $10 Cambridge Vendor License
$15 Additional Spaces
Admission is after the prepaid vendors

Early Bird Buyer -Admission after the prepaid vendor line is admitted. ~ 7:15AM
** You may not sell. **
$15 per person at the gate.

Haven't seen that catalog so I don't know what quality of parts MFJ
offers these days. But I can tell you that I've had to repair my
MFJ-949B tuner a couple of times over the years. The rotor of one of the
variable capacitors was making intermittent contact with the wiping
contact and needed fixing. The inductor switch is a cheap-looking pot
metal thing that had a couple of intermittent positions and I wound up
replacing it with a better switch. I wasn't impressed with the quality
of those components. I hope they're using better parts these days.

> Schafer 1975)

Delete the incorrect second Reference to Oppenheim and Willsky 1983.

> All of these results are related in principle to the Central Limit
> Theorem of statistics.

See http://mathworld.wolfram.com/CentralLimitTheorem.html for this
interesting topic. The general idea that the theorem alludes to in this
example is that as sharp-cornered filters are cascaded the passband response
becomes noticeably more rounded at the corners, similar to Bessel and
Gaussian filters.

Smoothing and Windowing methods can be used to reduce sharp corners in
discrete sequences such as digital filters (see Oppenheim and Schafer 1975
and many other sources).

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B

licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

Hi Guys,
Results of the build and test were that the 7Mhz HPF worked very well with the "6" grade cores, but the 20Mhz LPF was crap (it used #6 as well). It started to roll off at 20Mhz as expected, dropped smoothly to -10dB by the time it got to 40Mhz, then stayed at 10dB at all frequencies above 40Mhz. I suppose the core should be a grade #10 or #12 instead of #6? or perhaps just a normal air core?

Then you haven't built the filter that you designed. The choice of core material will not affect the blow-by. If you measured the inductors at a low frequency, I would be pretty certain that you have way too much inductance at 20-40 MHz.

Plasma physics research facility. 2-4 minute charge cycle, 70 mSec
discharge. These banks supply the crowbar, or "follow-on," current
once the big 5 kV banks have discharged down. Yes the charging
supplies are large, and the future ones will have to be even larger.
We tend to go for some kind of constant current scheme, up to the
preset voltage limit.

I don't think our leakage current is nearly as high as you suggest.
The caps tend to form nicely after awhile and the leakage current
ramps down with use. Until one fails, of course. ;-)

>A bank of 90 caps at 16000uf each looks like 1.4 farads. That's an
>incredible amount of storage at first look. The leakage alone on a bank like
>that would be about 400ma.

I rounded. We're actually shooting for individual banks of .3F at
900V, so that takes 1.2F of 450V caps, times 16 of these banks.
Charge/discharge is as above, leakage should be less that what you
suggest, but I could be wrong about that.

>In the linear amplifier, there are really a couple of things that tend to
>kill the caps. First, the ripple current tends to heat the caps, which are
>in a relatively warm location to begin with, sitting right next to a fairly
>large transformer, and a full wave bridge just above them.

I don't know how much internal heating you'll get, but temp is
certainly something to be concerned with. Our application stays pretty
much at room temp.

>However, given that I live in an area with less than perfect regulation of
>the incoming AC line, I tend to be a bit gun-shy about what I see personally

Did you consider upgrading the input bridge? I agree that excessive
line voltage is a problem, but the bridge was clearly your weak link.

>After the
>first failure, I instrumented the AC line and kept graphs on it. The line
>voltage ranged from 235 to 243 volts over the typical 24 hour period, and

>would rise to as much as 255 volts for brief periods of time (usually only a
>few seconds, but one prolonged instance went over 15 seconds).

I think the surge ratings for Al caps are for a 30 second surge.

>OK, not a long time, considering the really big picture,
>but looking inside the amplifier and seeing that three of the bridging
>resistors (50K ohm, 7 watts) and 4 of the capacitors were replaced at some
>time in its history, I am tending towards getting more margin into the
>design.

I agree that there's often room for improvement in amateur gear.
Upping the resistor power ratings might be useful, too. If they run in
the same ambient, then they should also be derated.

>My tolerance for failure is low. I would prefer to get this amplifier up to
>snuff, put it into service, and never have to open the case again.

I agree with your goal, and I don't think running 450V caps at 450V
will come back to haunt you. Just make sure that the 30 second surge
rating is above the highest voltage you think you'll ever see.

>Of course, in the back of my mind (and not previously mentioned) is the
>possibility of running the amplifier from the 220 volt tap on the
>transformer, which would give me 3925 volts nominal on the bank at 240 volts,
>and 4010 volts on the bank at 245 volts, and 4175 if I see the same sort of
>255 volt spike at the new QTH.

With 10 caps, that's still less than 420 V/cap. I don't think that's
any problem at all.

4603. 40/50 Mix toroid specs?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-17 00:24:44 UTC
From: TRABEM <>
Message-ID: <rnr5l1dk0qce2ngf62nqa20fs5f676td5u@4ax.com>
Source record: 16886

I have an old bag of toroids, I've had them for 25 years and I have no idea how long the previous owner had them before me.

The label on the bag says:

40/50 mix

They are about 15/16" OD, 9/16" and are 5/16" thick. They are green (ID/OD and one side) and yellow on the remaining surface.

I would like to use them in a frequency sensitive application, so I really need to know what a '40/50 mix' means.

I've googled, got nothing. When I included "toroid", got nothing even close when I left it out I got things like recipes, motor oil spec's etc.

I think the 40/50 mix is the old method of grading the material, but I can't seem to find anything about it on the web.

Any idea what this mix is good for?

Thanks,

T

Nope. Wind and test a few examples and you can probably get into a ballpark.

If they are power supply toroids vs rf toroids, or ferrite vs powdered iron, that will quickly become obvious. The way the surplus market goes, most "found" toroids are power supply types and only good for that application.

HP used to have a nice app note on this. The main trick is that the eye responds most nearly to intensity, which is close to being proportional to the square of the brightness (analogous to power vs voltage). Just like "pulsey" currents have higher RMS values, "pulsey" light can have a higher intensity. The eye acts as a smoothing filter. This is a well known trick in lots of lighting and display areas. If you really care, you can use LEDs as "catch" diodes in switching regulator circuits to get some pretty amazing "lumens per watt."

MFJ has a dubious quality reputation from comments around these parts. They make Ham quality stuff and you must expect that. I'm not saying it's bad, just not gold plated and super high quality. Remember quality = $$. (thought he converse isn't always true) My roller inductor developed an intermittent after a few years and I had to solder one of the contacts - hard to get to, but the thing works ok as far as I can tell.
I have an older one, I think 986, two knob "T". It has matched my 40M dipole on 75!

Good luck...However. I did find one Agilent ap note about LEDs , but it
didn't mention pulsed vs. non-pulsed brightness...much.

I did build a pulsed LED driver a long time ago. It used an inductor and
comparator. Turn on switch in series with LED, inductor (tried 1mH first)
and supply. When current ramps up to the desired, turn off switch. A
"catch" or "fly-wheel" diode then conducts current through LED & inductor
while current decays to a lower level where switch turns on. Neat to see
the supply current less than the LED current.

If I know only the power in dbm is there a formula to arrive at
vswr without conversion first to watts or volts?

outbound = +63dbm (2kw)
reflected = +36dbm (4w)

This is a waveguide system with a dummyload connected in
the event the numbers seem improper.

I would like to use the formula when we connect the real antenna.

Take the formula for calculating vswr from P in watts, previously converting
the dBm into W.
You'll get the following vswr=(1+10^(0.5*(Pout-Pref)))/(1-10^(0.5*(Pout-Pref))).

Hello, Mike,

I had a little experience with some military L-band RF design (JTIDS), but that is about all. I have also designed miniature lumped-element filters for the 3 GHz region. But most of my work and also my ham radio experience have been at HF. Also, I am mostly, but not entirely, an analog specialist, which has put me somewhat into the Jurassic Age.

Not really. Newly minted engineers know remarkably little about analog techniques. Yet at the beginning and the end of circuits stuff usually needs to connect to the analog world. So don't be surprised when someone begs you to do just one more stint when you are past 90.

Then again a SW engineer once told me that nothing is truly analog. There is always that smallest digital step, the quantum.

There is no reason to apologize for being good with analog. ;-) I
worked as a broadcast engineer during the time they announced the first
memory chip, (1101) which was a slow, noisy 256 bit * 1 DRAM with very
critical timing. I also did analog and digital work on the microwave
equipment built at Microdyne, before L3-Com closed the Ocala plant.

The reason I asked about the microwave equipment, I would like to
meet the people who designed the C-band CATV receivers I had to maintain
in the '80s. I always loved Collins equipment, till I ran into those
radios. They had a horrible failure rate, and took over six months to
have serviced by Collins. I think I still have a set of manuals for
the fixed tuned, and the agile models. I started repairing them for
United Video in 1982, and could return most of them to service the same
day.

Seems you started with digital stuff a year or two earlier than I did.
My first RAM had a whopping 1024 bits. Not bytes, bits. 21...something,
I could look it up since the device where its in still works.

> The reason I asked about the microwave equipment, I would like to

I still have an unused 2.1 KHz Collins 455 KHz mechanical filter I
bought at the Dayton hamfest years ago. Its a little narrow for voice,
but it would be good for CW.

I still like Collins equipment, just not their poorly designed CATV
equipment. I wish I could afford a R-390 and felt well enough to do a
complete restoration. :(

Vector network analyzer:

http://www.tapr.org/kits_vna.html?PHPSESSID=a7dc69d72fed0dac75d27069f244
0fa7

Or, if you can't hack fine-pitch boards, you can buy it assembled and
tested: ($655)

http://radio.tentec.com/Amateur/vna

measurements:

S21 Magnitude: gain or loss of two-port network from input to output.

S21 Phase: the transfer phase of two-port network from input to output.

S11 Magnitude: return loss of one-port or two-port network referenced
to input of the network.

S11 Phase: the phase angle of return loss of one-port or two-port
network referenced to input of network.

Specifications

Frequency Range: 1 MHz-100 MHz at full specification. Operational with
degraded performance up to 120 MHz and down to 200 kHz.

Resolution:
.1 dB for amplitude measurements
1 degree for phase measurements

Dynamic Range:
in forward mode, 80 dB at lower frequencies
75 dB mid-range and higher frequencies

In reverse mode, -35 dB at lower frequencies
-25 dB at mid-range and higher frequencies

Output Power: nominal +3 dBm (approx. 2 mw) at TRANSMIT connector

Maximum Input Level: +10 dBm (2 V P-P) into TRANSMIT or RECEIVE
connector.

Requirements for host PC: Windows 98SE, 2000 or XP. Also requires
Windows installer program and .NET 1.1 framework (provided on CD) run
time package.

Not as good as the Agilent box I have in the lab, but the Agilent box
costs more than my car...

4629. best material for turning a closet into a Faraday cage

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-19 05:13:36 UTC
From: eternalsquire@comcast.net
Message-ID: <1129698816.759523.298440@g43g2000cwa.googlegroups.com>
Source record: 16762

All,

I have the opportunity to turn a walk-in closet with door into a ham station. I'm thinking of turning the closet into a Faraday cage to help in reducing common-mode QRM. To this this, I will need to line the entire inside of the closet, including the door, with some type of metal, and then connect that metal to my ground system.

Question is this: what type of metal would provide acceptable results: aluminum foil, copper foil, or tin-plated zinc sheets nailed overlapping along the closet inside?

Thanks in advance,

The Eternal Squire

4630. Shunt feedback in broadband RF amps

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-19 05:58:55 UTC
From: meara.london@virgin.net
Message-ID: <1129701535.404399.192870@f14g2000cwb.googlegroups.com>
Source record: 16763

I'm having trouble understanding how the typical shunt feedback networks used in RF (solid state) amps work. I'm looking at the 1993 ARRL Handbook. Typical common base broadband amp. For the shunt feedback (from collector to base) they have two resistors: 560 ohms in series with 3300 ohms. The 3300 ohm is bypassed by a .01 uf cap.

So far so good. But then the text explains that because you have rising gain characteristics when the frequency drops you need something to reduce gain at lower frequencies. That's why the negative feedback helps.

Here's where I'm having trouble: "As the operating frequency is decreased the negative feedback increases becasue the network feedback reactance becomes lower." Huh? Wouldn't that network's reactance INCREASE as frequency is lowered? The only part of it with reactance is the .01 cap, correct?

Help! 73!

Source record: 16764

HI,

I'm building a 40m rig, using the transmitter part of the "Miss Moskita" .
(German rig "QrpProject" : NE602-BF199-BFR96-2SC1969).
Unfortunately, it doesn't work.
I spent a lot of time (2 months) to find the mistake without any result.
At last, I changed ALL the parts of the circuit without result.

Could someone give me the voltage I should have at (DC and peak/peak).

NE602 pin 1 (I have 50mVpp 12mHz)
NE602 pin 6 (I have 0.6Vpp 4.91mHz)
NE602 pin 4-5 (I have 0.2V pp 7mHz...)
Base BF199 (I have 25mVpp and 0.75VDC)
Base BFR96 (I have 1.2Vpp)
Collector BFR96 (I have 10Vpp and 8VDC)
Base 2SC1969 (I have 2V pp)

I'm very tired...;o(
Thanks a lot for your help.

Dan

Just as important as the conductivity and thickness of the shield is
the continuity. Nonconducting seams can act as slot antennas. So
aluminum, though it is a very good conductor, is very difficult to
seam in a conductive way. Well connected, galvanized chicken wire
(with 1 inch or so holes) may work as well as aluminum foil that has
non conductive seams, as long as the holes are much smaller than the
shortest wavelengths you are trying to shield.

I think the capacitor is large enough that you can consider it a short circuit for all frequencies (above 1/(2*pi*3300*.01*10^6)=4.8kHz). So the author has confused himself about that. The feedback passes through an effectively a constant impedance of 560 ohms. The 3300 ohm resistor and capacitor are just there to set the DC operating point. As the low frequency gain rises, the feedback current increases as the output voltage tries to increase, but this has nothing to do with a change in the feedback path impedance.

Nah - 2102 1k * 1.

Had 8 of 'em in in my homebuilt Nascom 1 computer which with a
2708 UVEPROM for the 'monitor' was all the RAM for system and
user code and video store! Nevertheless, it was sufficient for a
machine code program to run 'Lunar Lander', hee hee.

Collins filters were regarded as the bees knees in UK ham circles
but I never could afford one!

In the 1994 RAH the same reference is in section 4 figure 53C.

There are TWO feedback networks. One in the emitter circuit
and the Collector Base feedback. Ther is also the transformer
that will limit low frequecy response as a secondary action
which also limits Collector feedback as well.

However, they are refering to the RC pair found on the leg of the
emitter. For that case the statement would be correct.

Typically those amps (unless higher power) the emitter has a bias
resistor. That resistor is bypassed with a RC of .1 or .01uF and
series R of a few ohms (typically less than 20 ohms). That C is
fairly small for low RF and audio to effectively bypass the emitter
circuit. so at say DC and audio the Emitter resistance is 110ohms.
At some greater frequency the capacitor looks like a very low
reactance and the emitter resistance is effectively 10 ohms at RF.

That emitter network allows setting DCbias (operating point) and also
the AC feedback at the Emitter Base leg. Since the capacitor
has greater reactance at low frequencies the feedback is greater.

The RAH has only a very terse description and lacks design detail.
If you look at Solid State Design for the Radio Amateur (ARRL press)
and/or Exprimental Methods in RF Design (ARRL press) you will
have a far more detailed explanation of how that amplifier works and
how to calculate values for design.

Hope that helps.

Allison

There are very few good reassons for doing this. There are also
considerations such as any thing that comes in must be bypassed
and filtered (I really mean everthing) so that none of the offending
signals arrive. AC power is the hardest to filter.

The best material and common most one is Copper screening.
Note ALL joints must be soldered or otherwise have a non corroding
and solid joint. The door also must have a 100% contact joint all the
way around (bottom too). The door will usually have phosphor bronze
allow fingers to allow contact around the periphery. What your
attempting to make is a box that has no openings that are
significant till you reach the microwave range.

Why is common mode QRM a big problem?

Allison

Out here in the this trailer park, we have both dirty power coming from
the AC, and air-conditioning motors from a whole bunch of trailers.
These are problems that cannot be fixed, so I would rather use
defensive techniques such as a Faraday cage

A Faraday cage is an electrostatic shield, not a shield for electromagnetic fields(*). There would be no advantage to shielding your equipment from external electrostatic fields.

Shielding your station from electromagnetic fields probably won't solve any perceived problems, either, and is a much more difficult job. As others have pointed out, it's often much more difficult to prevent energy from getting through the shield via power and other conductors and through seams and door fittings than it is to make the shield itself. If you don't pay proper attention to the sneak paths where energy can get in, you're wasting your time making the shield in the first place.

(*) I found "Faraday cage" in the index of only one of a half dozen electromagnetics texts. It's not in Terman's _Radio Engineering_ or the rather old IEEE dictionary I have, either.

Lungren screen rooms use a copper screen which is just like screen door.
However, they are rated up into the GHz range. You'll also need some type
of "finger stock" around the door to provide an electrical seal. The
Lungren screen rooms have a brass-like finger stock all around the door.
The grounds _ALL_ go to one single point and only one single point

However... I'm not sure what this buys you for a ham shack...unless you want
to do receiver design and testing and need the quiet, RF free environment.
Connecting the antenna eliminates all your work, so to speak.

In the 70's I worked on 150 MHz PA's and we used what we called a
"banana". It was called that because once one got fried and afterward it
looked like a cooked banana. It was a orange drop (dipped) cap (I think
mylar), value forgotten - somewhere in the .001 - .01 range, with two 1/4
watt resistors in series, one at each end that held it up over the power
transistor.
Though I don't remember if they were ever measured, the rationale was
that these caps had considerable inductance at 150 MHz. and were thus an
"open" there. Down in the 1-20 MHz range, where the regen (regeneration -
oscillation) occurred, they were a "short". Also remember that the
transistor impedances are in the .1-1 ohm range for power devices. I think
we also may have put small, 50 ohm, beads on the resistor leads. If the
bead exploded, you knew you hadn't sloved the regen problem because there
was considerable energy at the regen frequency. and thay became good loads.

For regen there are the "dancing faintlies" and the "christmas tree" types.
(:-)

Forget not those parasitics in the components.

I'm sorry to mention this, but yes, I am a builder, and its very hard to do low-level measurements. I was hoping that feeding my antenna connection through a bypassed and filtered port would allow my signals in but without the common-mode AC and motor noise.

Won't work. Most of the noise is radiated and the point of
interaction is the antenna not the power cord for the most part.

If the power source really is dirty try running on isolated battery
or from the mobile rig in the car. IF you hear it there then you need
to get away from the area.

FYI: the motors used for air conditioning and refigeration are least
likely noise sources. Most are capcitor start induction types, arcing
or other raditional likely sources are not common to them.

Electonics such as TVs, Computers, Electronic Games, Lamp
dimmers and touch switches are your enemies.

Having tamed a few solid state power amps I can appreciate that.
However this is not a similar case.

The amplifier in question is of the lower power (under 50mW) type
commonly used for wide band amplifiers and/or RF amps at low levels.
The question really stems from a far too brief description of said amp
in the handbook.

Check this article out.

www.qsl.net/n9zia/wireless/pdf/julaug1998-p64.pdf

It's an article about making a shielded room from foil covered foam board. You'd still have the problem of getting your power in, and signal cable out. Actually, the signal cable out would be fairly easy. Bulkhead mounted type-N or SMA connectors are made just for that purpose. The power would be slightly more difficult. Not only do you want to keep stray RF from leaking through the hole, but it would require filtering to reduce conducted noise on the lines also. One of my first real jobs was at an commerical two-way dealer. The shop, and tower were really close (less than a mile) to a 50 kW AM broadcaster (WTOP 1500 kHz). Guess how I discovered 60 volts AC between the cases of two AC outlets. I also learned that a 3 dB reduction in reciever sensitivity makes a big difference, but reducing the noise level by 3 dB doesn't.

Come to think of it, of all the screen rooms, and sheet metal shielded rooms I've ever been in the biggest problem was ventilation.

Allison: Thanks.

Obviously you are right. But I see the same kind of confusing language in other editions of the handbook. In the 1980 edition (otherwise one of my favorites) they have (pg 6-19) a collector-base feedback network with just a cap and a resistor in series. Text reads: "C1 and R3 provide negative feedback which increases progressively as the frequency is lowered." It calls for a cap of values between 220 pf and .00015 for hf band amps, IN SERIES with a resistor of from 51 to 5600 ohms.

Is this just a case of some confusing language that has kind of worked its way in the handbook DNA and is passed down from generation to generation? Or is there really something about these cap and resistor in series networks that cause them to increase the amount of feedback as freq drops?

Friend,
Check out http://ChezBrandon.com As are you, Brandon is highly intelligent, knowledgeable, and good. May you have an awesome day.
A Succinct Warning: Elements of Mossad, sated with cash from the murderous and destructive narcotics trade - for example, according to Reader's Digest, cocaine alone costs US businesses $50+ billion per year (!) - are using some medical, pharmacy, and food service workers to murder men, women, and children. (A certain tasteless acid, for instance, causes cancer.) Victor Ostrovsky's book By Way of Deception and James Ennes, Jr.'s Assault on the Liberty offer other elucidation as does the following Daily News article:
www.dailynews.lk/2005/03/01/fea10.html
President of the International Narcotics Control Board, Philip Emafo, put it excellently when he stated: "Drug trafficking does not contribute to economic growth and prosperity [rather it] destabilizes the state, the economy, and civil society apart from the damage to long-term economic development." On top of this, elements of Mossad have decided to become serial-killers/terrorists and murder men, women, and children.

That reference is definately an error. The only way that would be
expected to occur is when the C is sufficiently large enough to be
useful at lower frequencies. Often enough it was.

Amplifiers of that type and time use transistors of say FT 150mhz
and a betacutoff of 1 to 3 mhz. What happen is as you go up in
frequency from 1 to say 30 mhz the effective AC beta goes from
about 100 down to 5. The amplifier gain also has that same
downward curve. It's that rising gain when progressing down in
frequency your working against with the described network.
So when that allowed for and the series C and R it's is possible
to say that as the feedback increases as the gain increases.
Even then without putting boundaries on the values and using
a real (working) circuit it's not a good explanation and borders
on error.

The "yabut" of amplifiers (that one being a class C poweramp)
is that EVERYthing around the transistor interacts due to the low
impedences and high currents. So by observation that circuit
may actually work somewhat as described but likely there are
onter factors at work that are not well explained there.

Examples of this (same circuit P6-19) that can cause grief. The
bypass on the collector circuit needs to be effective at audio through

RF and yet the schematic only shows one cap. The likely circuit when built would not be stable.

I think again that explanations suffers from trying to be too brief and leaving out detail. When examined without full context appears to be an error can still have validity. The RAH is a good text, lots of information and relatively few errors. However it's only one source and even they cite other sources for greater detail. Failure to take advantage of those citations and delve deeper can lead to believeing in lore rather than studied consideration.

The 1994 ARRL handbook, page 4-23, Fig 53C shows the feedback amplifier that you describe. However, it is a common-emitter circuit, not a common-base circuit. The 3300 ohm resistor returns to +12 V DC and provides DC base current for the 2N5109. The 0.01 uF bypass makes the 560 ohm resistor the main source of this feedback at radio frequencies.

There are two kinds of feedback in the circuit. One is the 560 ohms in the base circuit. The author calls this "negative feedback". I call this "voltage feedback". This feedback does not change very much over the HF region.

The other feedback (he calls it "degenerative feedback") is a 10 ohm resistor in the emitter in series with a 100 resistor which is shunted by 0.01uF. I call this "current feedback". This feedback increases at low radio frequency because the impedance from emitter to ground increases at low radio frequencies. This is the feedback that the text is referring to in the text and it is correct. This kind of feedback increases at low frequency. If the 0.01 uF were replaced by a 1.0 uF this increase in feedback would be a lot less at low radio frequencies.

The author, probably DeMaw, got his terminology slightly mixed up but he is referring to the emitter to ground current feedback, not the collector to base voltage feedback.

If you have a copy of the 2004 Handbook, chapter 17 has a sidebar discussion of negative feedback that is interesting. Later editions may have deleted it.

Sort of ...

The Return Loss is 63dBm - 36dBm => 27dB (that's very good!)

Converting to reflection coefficient, Gamma = 10^(-27dB/20) => 0.0447

Then, VSWR = (Gamma + 1)/(Gamma-1) => 1.09 : 1

No volts or watts but, to be honest, Gamma is a voltage ratio ... :-)

Hope that helped,
Darrell ...

I think to actually figure this out you will need to write the gain transfer equation for the amplifier. Many of the replies here are talking about an RF amplifier but are analyzing the feedback at DC.

Remember that the output of a transistor is NOT in phase with the input. As the base voltage goes UP the collector voltage goes DOWN. (think of a transistor used as a switch - when the base is biased off the no current flows and the collector is at power supply potential - when the switch is biased on then current flows and the collector is driven toward the potential of the emitter -- i.e. the collector voltage goes down) For RF the actual phase difference between input and output is dependent upon the input and output impedances of the transistor as well as the gain transfer characteristic (things like transit times of the current carriers and junctions widths and all sorts of stuff figure in here). *THEN* you have to consider the phase contribution of the RC network in the collector to base network. At some RF frequency the collector is 180deg out of phase with the input so a direct feedback link from the collector to the base would be *negative*. It is quite possible that the phase relationships of this particular amplifier are such that the negative feedback increases as the

frequency goes down.

You would just have to write the equations and see where they take you.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B

licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

Because although CBers are in a different intellectual
class to Radio Hams, it is neither my wish to insult
them nor to enter into a discourse with them.

CBers have the right to besport their habits in the
appropriate place as do all the lower classes, which
in this context is rrcb (and urrcb).

You just demonstrated that you are one of the worst discrimination
idiots I
have ever met on Usenet, and I have been on Usenet for 13 years.
On radio much much longer.
Look little motherf*cker, there are even professors on CB.
And there are clearly complete idiots like you that accidently got
an amateur radio license on the amateur bands.

Even if you get an amateur license, you are STILL an amateur.

Actually I worked in professional broadcasting and designed
professional
transmitters.
You just convinced me NOT to listen on amateur frequencies.
F*cking idiot moron.
hehe

Ham Radio is a hobby for the type of people who would be in local
government but got thrown out for not being progressive enough. If your
favourite hobby is hosting a committee or writing a new regulation then
this is the hobby for you.

To be a "proper" radio amateur you agree with one or more of the following :

1) I've voted Tory all my life
2) Im Over 50
3) Im Buracratic
4) I smoke a pipe or cigar
5) Im not a racist, I just don't like
-Foreign people
-People who speak differently
-People who are not the same colour as me

6) HF is the one true mode, real radio doesn't use a microphone
7) In my day it was all CW *yawn*
8) Repeaters are for morons
9) Dam young people, fools the lot of them ra ra ra ! Join the RSGB ...
10) Data isn't a 'real' mode
11) Whats wrong with the licence as it is - I see nothing wrong.
12) You should have a NOV for anything that hasn't already been excluded
by the licence
13) Nothing interesting happens above 30Mhz
14) I know all about computers, thats why I hate them
15) I'm a shit hot designer - my radio was designed by a small yellow man
with more skill than me, but im not angry (see 5)
16) I make my own wire antennas that makes me an RF designer
17) People with less skill than me are worthless

If you identify with this then this is the hobby for you. But hurry, be
quick - when all the stupid old fuckers have died out then nobody will be
left ....

Not difficult to deduce that you are a CB-er.

I'm going to take your test...

> 1) I've voted Tory all my life

Nope. In fact, I haven't voted for a long time.

> 2) Im Over 50

Nope.

> 3) Im Buracratic

Absolutely not.

> 4) I smoke a pipe or cigar

Wrong again.

> 5) Im not a racist, I just don't like
> -Foreign people

Not true. I know several, and I like them. I also enjoy DX.

> -People who speak differently

Not a problem.

> -People who are not the same colour as me

What "colour" would that be ?

> 6) HF is the one true mode, real radio doesn't use a microphone

I find HF more interesting than higher frequencies, because it allows me to
communicate with people across the globe. CW is my favorite mode, but that
doesn't mean I think there's anything less "real" about other modes.

> 7) In my day it was all CW *yawn*

Actually, it was. When I got my license, CW was all I was allowed to do.
And it was really interesting, too.

> 8) Repeaters are for morons

They ARE ? How come ?

> 9) Dam young people, fools the lot of them ra ra ra ! Join the RSGB

I don't have anything against young people. As a matter of fact, I live
with a couple of those and I frequently meet other kids.

> ... 10) Data isn't a 'real' mode

It's real. But to me it's not all that interesting.

> 11) Whats wrong with the licence as it is - I see nothing wrong.

Me neither. So what IS wrong with it ?

> 12) You should have a NOV for anything that hasn't already been
> excluded
> by the licence

What's a NOV and how can I get one ?

> 13) Nothing interesting happens above 30Mhz

Not true at all.

> 14) I know all about computers, thats why I hate them

I know a lot about computers, I work with them for a living. And that is
one of the main reason for my interest in ham radio.

> 15) I'm a shit hot designer - my radio was designed by a small yellow
> man with more skill than me, but im not angry (see 5)

Completely wrong.

> 16) I make my own wire antennas that makes me an RF designer

I might make my own antennas, but that doesn't make me anything. It might
make my radio function better, tho.

> 17) People with less skill than me are worthless

Only when they behave as if they know everything.

> If you identify with this then this is the hobby for you.

Obviously, it's not the hobby for me, then. So how come I'm staying at it ?

> But hurry, be quick - when all the stupid old fuckers have died out
> then nobody will be left ....

Nobody are more helpful than those "stupid old fuckers" so that will be a sad day.

Hold about a bit matey boy... Just because someone uses a CB doesnt make them a lower class person or less intellectual than an Amateur radio user. They may have brains far exceeding yours on several topics, just not on radio. Just because you know a bit about radio doesnt make you a higher class of person... IT JUST MEANS YOU KNOW ABOUT RADIO'S..... now try learning common sense, respect for ones fellow man and remember.. Amateur Radio.. Just like CB.. is JUST A HOBBY...
I love the bit though where you say "it is neither my wish to insult them" but you manage to do it anyhow...
10-4 over and out .. or in your case QRT..

Poly Parrot has forgotten he has owned a CB and a license (still does, I expect), ignore him.. having been arrested he is a prime example of what amateur radio has descended to.

Unbeknown to me, this thread had already been cross-posted to
the CB groups, and I would have removed that cross-posting
had I been aware of it.

In respect of that, I apologise if my remarks have caused
any offence to the CB community. However, I do not
withdraw my remarks - they are my opinion as to the
relative standing of Radio Hams and of CB Radio
enthusiasts where the playing-field is that of Radio
Hams.

However, having said that, the material quoted below
serves, I think, to illustrate quite well the
intellectual standing of CB Radio enthusiasts
upon which I have commented.....

Harry, I checked and I found them still listed (eBay store). Apparently the the url I gave was defective---perhaps cut and paste the entire link into browser to get to them or do a eBay search for Alfred Morgan. There is also a 'second boy's book' for auction with bidding at $31.

Maybe I'm slow but I have yet to find a way to properly post those page long urls so as to make a 1-click link.

Cross-posted to: uk.radio.amateur,rec.radio.amateur.homebrew,rec.radio.amateur.policy

REAL Ham Radio is a technical pursuit.

One area that remains easily open is the construction
of CW rigs - you need little more than an
oscillator.

Off-the-shelf talk-boxes are the stuff of which
CB is made, and not Ham Radio.

Therefore let us move to ban voice communications
from Ham Radio - a listen to 20m shows up inane
conversations from CB types only.

CW comms has always been the essence of Ham Radio,
and remains a feature of Ham Radio now that the
commercial world has moved into Sat comms.

So.....
1. Restore the 12 WPM Morse test around the world.
2. Cancel _ALL_ licences where the licensee has not
passed a 12 WPM Morse Test.
3. Remove all band plans - only Morse is now allowed.
4. All new licensees to be limited to their first year
op operation to 10W home-brewed rigs (And, of course,
on CW as there will be no more voice)
Let us fight the insidious march of the Mongolian
Hordes of CBers-Masquerading-As-Radio-Hams before it
is far too late!

In the realms of talking specifically about radio apology accepted but
everyone swears at some time. Amateurs included. While i dont condone it i
can understand it. If you upset someone enough you "will" get this sort of
response. Im a CB'er by the way.
Regards,
Graham

Do you know, in all my years of CB radio use ive never actually heard anyone talk like that on the CB. Ive been on since 1979 (not continuously, i do let go the mic occasionally ;o) The only people who talk like that are people who have no real idea of CB and are just taking the Mick. Am i wrong?? do people talk like that on the CB where you live?? Let us know where these people are so we can avoid them ....

Hi Hully,
Unfortunately there are a few like him on the Amateur band. Its a shame really. Its meant to be a hobby after all and his attitude will put many prospective new Amateurs off as they will see it as an unfriendly place. Not good for the cause..
Regards,
Graham

Indeed. He claims to have both a now obsolete advanced ham ticket,
(unlikely) and a pilot's license (highly unlikely.)! But he hides
behind a cheezy handle swiped from a cheezy 50's sci-fi show.

He nym shifts too, he used to post as "JJ" from that TV show goodtimes..his
CB handle was 'kid dynomite' back in the CB boom of the 70's. What a putz.

4714. impedance of 2x 4cx800a ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-22 19:15:35 UTC
From: James Skalski <jskalski@yahoo.com>
Message-ID: <rdw6f.2811$%A1.284@trndny01>
Source record: 16747

What is the plate load impedance of a pair of 4cx800A tubes run at
2500VDC and 1500 watts out?
I have read varying opinions on the amp groups ranging from 800ohms to
2100 ohms. I thought it might be 1600 ohms. :)
Once the impedance is known I can try to determine the minimum tuning
capacitance that I need.
The pair of tubes are 22pf. What would be guesstimate of the stray
capacitance in the tank circuit?

I am undecided if I will use Pi or Pi-L network and whether it will be a
load of 50 ohm or 200ohms with a toroid to bring it down to 50 ohms. I
have to use real world parts....

I can use a vacuum cap to keep things simple.
since I am not an engineer, I want to be sure that my guesses are in the
ballpark...

any input would be appreciated.

Last time that I built an amp was over twenty years ago. It was a
4-1000a and I built the Hypersil plate transformer by hand winding it :)
This time I will have Peter Dahl earn his money.

Jim n2go

The Armenian judges gave this a 9.8 on the Olympic Troll-O-Meter,
but they were overruled by the umpires in instant replay, who
awarded it a 2.6.

The Armenian judges lodged a formal protest!

It was sufficiently trollish, of course, but way too obvious.
It was poorly written, poorly executed, and was so incredibly
lame as to lack the true drawing power of a really masterful
troll. Maybe as high as a 3.1 for the intense stupidity of the
premise, but a 9.8? Never! The Armenian judges tear their
hair out, throw their balalaikas down in dismay, and perform
the traditional Armenian Dismay Chant! They demand a recount!

Depends on what class of operation you intend and on the screen
voltage.

The best way to determine it is using the Eimac Tube Peformance
Calculator, which was a graphical way to implement Chaffee's method.

This is described in "Care and Feeding of Power Grid Tubes" section 3,
which can be found online at:

http://www.cpii.com/eimac/PDF/C&F3Web.pdf

Probably figure 5-10 pF.

I would not use a transformer here.

With your plate voltage you might not need the vacuum cap but it won't
hurt and the minimum C will be an advantage.

4723. High Q caps for 60 Khz loop antenna?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-23 03:58:10 UTC
From: TRABEM <>
Message-ID: <jpvll1tsjafrmsgmoskph4td69hc88ccpt@4ax.com>
Source record: 16656

What caps should I use for a resonant loop antenna for VLF? I have some antenna plans and need .2 uf total capacitance to resonate a loop antenna at 60 Khz.

I know I should avoid electrolytic and tantalum due to their poor temperature stability.

Disc ceramics are so poor thermally that they are out of the question, especially since the caps are going to be outdoors.

Silver Mica's are horribly expensive these days, and aren't available much past .01uf anyway.

I have a Mouser catalog and plan to order from them soon, but it's not clear which type of cap I should order.

Any suggestions for 50,000 pF caps that don't cost a fortune?

Note that this is a receive only antenna so voltage rating and current carrying capacity are not an issue.

Thanks.

4725. Using a Y5V dielectric capacitor for tuning

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-23 04:15:35 UTC
From: Joel Kolstad <JKolstad71HatesSpam@yahoo.com>
Message-ID: <11lm3mgh6s2l879@corp.supernews.com>
Source record: 16658

I came across this link: https://www.avx.com/docs/techinfo/mlc-tant.pdf ... which points out that Y5V dielectric capacitors chance their effective capacitance across about a 5:1 range depending on the DC basis. Has anyone used this "feature" to obtain tuning in a radio? Similar to using a varactor diode's capacitance for the same effect? I'm thinking that it might not work as well as a varactor diode (especially given Y5V's very significant temperature dependence), but it still seems like it could be a novel idea for a low parts count receiver that didn't need particularly stable tuning.

Some possibilities might be polystyrene and metalized polypropylene.
They will be large, but not so expensive in that size.

4727. Re: High Q caps for 60 Khz loop antenna?

Thanks John,

I did find metalized polypropylene caps in the Mouser catalog. Some
are quite expensive for no apparent reason and a few are inexpensive.
I still don't know why the big cost difference.

There were many pages of metalized polyester film caps, not sure if
they are ok or not. But, they are way cheaper, about half the price of
the lowest priced metalized polystyrene caps.

Are metalized polyester caps just as good as metalized polypropylene
caps?

Thanks,

T

Is there any possibility that you could add turns to your loop, to
lower the size of the capacitor needed?

I have, without much success. They used non-standard modem tones and
data rates. (probably to discourage spoofing)

I wonder if the easiest way might be to cannibalize a S.A.M.E. weather
radio? You could even tap the warning lights to signal the repeater
when an alert is present, and simply use the programming of the weather
radio to decide which alerts to relay.

Agreed. Locally here they have been advertising EAS type consumer
radios. From what I gather from the blurb they seem like the real thing
with programmable municipality codes, programmable to your choice of
alert tones, etc. I don't know what a S.A.M.E. is , maybe the same
thing ? (Oops, sri for the pun)
I haven't bothered to hear a brand name or price but I suspect its cheap
enough to negate building your own from scratch.

Good luck,
Bill

A cult you say? A dividing point you say? Who is the leader of this cult Markie? Do we stand around NAKED in a circle and summon demons?

A dividing point? What might that be Markie? The CW qualified, and the NOT? Why is THAT such a problem to you? Because your too LAZY to memorize enough Morse to pass a multiple GUESS test at the ridicolous slow speed of FIVE WORDS A MINUTE? You could pass that by knowing 15 letters and guessing at the rest.

I think the word of interest here is LAZY.

Continue Markey.....I can hardly wait.

Hi,

>My HP Q meter has a duff MPS6543 transistor.
>Anyone have one or know where I can obtain one?

According to the data sheet the MPS6543 isn't particularly unusual and you should be able to substitute if you don't find the real thing.

Have a look here -

http://www.datasheet4u.com/

It is a general-purpose, 350mW, 25V, UHF, silicon, NPN device with an FT of 750MHz, an HFE(min) of 25 and a Cob of 1.0pF in a TO-92 case with the emitter lead in the middle. Maplin have some transistors that might do in their High Frequency, Low Power NPN listing - possibly the BF199?.

BTW, I saw your posting on the HP_Agilent Yahoo Group and meant to reply then but forgot.

Cheers - Joe

4749. High Q caps for 60 Khz loop antenna?

--- on the heady topic of "High Q caps for 60 Khz loop antenna?"

Hi,

60KHz really isn't all that demanding. How about polycarbonate,
polystyrene, or mylar? The cheaper the better for receiving.
There are 0,22uF and lower standard value caps in all the above types.
Polystyrene are possibly the more stable but more easily damaged by
the heat of soldering. Just heatsink the lead with needlenose pliers
as close to the body as possible while soldering.

Hi John,

The loop is already bigger then my house and buying the large diameter wire to make it was not cheap. Buying an additional length just to add another turn would not be easy on me physically. Further, the R(ac), and therefore the Q would suffer since the loops resistance is now doubled by the addition of a second turn.

I am going to feed this into a quadrature front end, which has a problem with harmonics getting into the receiver. My hope is to use the loop as the sole tuning for the front end of the receiver, so maintaining the highest possible Q is imperative.

In terms of labor and cost, it is much more practical to use a larger value capacitor to get higher Q than it would be to use larger cable and more turns of it for the loop.

So, I will try to stick with the larger diameter single turn loop, which I why I asked for suggestions on which type of capacatior to buy to resonate the loop with.

Thanks to all who replied. I appreciate all the comments.

OK John,

I didn't realize that a polyester cap was the same as a 'mylar' cap.
But, it makes sense now that I know.

Some polyester film caps are pretty inexpensive. I might have gone for
them if I didn't need all the Q I can get for this particular antenna.

Thanks for the tip and to all who commented.

All this makes sense.

> Further, the R(ac),
> and therefore the Q would suffer since the loops resistance is now
> doubled by the addition of a second turn.

This, however, doesn't, necessarily. The resistance would double, but
the inductance would quadruple. The impedance would also quagruple
from about 119 ohms to 476 ohms, so the Q would roughly double when
tuned with a .055 uF capacitor. This, of course, neglects the loading
effect of the receiver input resistance and the radiation resistance
of the loop, and the eddy current loading of nearby conducting objects.

> I am going to feed this into a quadrature front end, which has a
> problem with harmonics getting into the receiver. My hope is to use

Understood.

> In terms of labor and cost, it is much more practical to use a

I can certainly see the cost advantage. Even an expensive capacitor
is probably cheaper than more wire.

> So, I will try to stick with the larger diameter single turn loop,
> which I why I asked for suggestions on which type of capacatior

(snip)

Makes lots more sense, now that I understand you are not using a
ferrite rod antenna.

Gee, and here I thought the FCC was acting on behalf of the ARRL
lobby..... easier tests = more hams = more revenue from RAH sales,
membership dues, sponsor organizations, federal grants, etc, etc.

The 5:1 range is more than I remember. All class 2 ceramics will do
this to some extent, but the nonlinear tempco is the drawback.

Varactor diodes have a much smaller C range, but that can be dealt
with.

Steveo can't even get a no-code tech.

4758. Wideband RF blocking

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-24 03:26:37 UTC
From: Joel Kolstad <JKolstad71HatesSpam@yahoo.com>
Message-ID: <11lol6n6q2qsjc0@corp.supernews.com>
Source record: 16691

In a receiver, for wideband (10-150MHz) biasing of a MMIC amplifier using inductors between the RF trace and the power rails, I'm finding that a single inductor tends not to work so well due to (1) wanting a largish inductor (say, one with 500 ohms of reactance at 10MHz in a 50 ohm system --> 8uH) but (2) not going beyond the self-resonant frequency of the inductor, which of course is smaller the larger the inductance (that 8uH inductor might typically have an SRF of 50MHz, noticeably below the 150MHz I'm trying to achieve RF blocking to!).

Is there a better means of providing wideband DC biasing/RF blocking than just placing a large and small inductor in series? I've run SPICE simulations of this, and -- just as when you stack multiple capacitors in parallel for wider RF coupling -- there are significant anti-resonances that drop the overall reactance of the pair of inductors to much less than 500 ohm (even less than 50 ohms!) unless you're very careful in the choice of individual inductor SRFs, inductances, etc.

Thanks,
---Joel Kolstad

Before going to such extreme measures, are you absolutely sure that the "harmonics" are entering the receiver from the actual loop due to insufficient Q and _not_ sneaking in through the cable shield, power supply lines etc. or other antenna effects ?

Even if you have a single strong unwanted signal at some harmonic frequency, taking it out with a high-Q notch filter prior to the mixer(s) would be easier. An isolation stage (emitter follower etc.) might be needed between the receiver loop and the notch filter to prevent too much interaction.

I should get one, wipe my ass with it and send it to the FCC.

4762. 4CX250B amp, with lumped output tuning

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-24 07:56:14 UTC
From: MarkAren <markaren10@yahoo.com>
Message-ID: <1130140574.864981.323150@f14g2000cwb.googlegroups.com>
Source record: 16695

Hi All,

I am contemplating the design of a class C amp for 144MHz using wound output inductors and a split stator (butterfly) tuning cap. This seems to be a very common approach in the good old days for QQV06-40As, but I don't think that I have seen such a design for 250Bs in push pull.

The issue of voltage rating of the o/p cap is of course an issue, and the output coupling loop will need to be well insulated (assume 1500VDC on the anodes).

Any obvious reason that this isn't a common approach ?

Ian ? Anyone ??

Thanks,

Mark.

<ouch!>

S.A.M.E. = Specific Area Message Encoding. It decodes the EAS bursts so
you can program it to only respond to alerts for your area, as opposed
to the older radios that keyed on the alert tone & would go off for
everything.

> I haven't bothered to hear a brand name or price but I suspect its cheap
> enough to negate building your own from scratch.

Radio Shack sells them, for well under $100. However, the model I had
can only be programmed for location, not for alert type. (i.e. you can
program which counties it'll go off for, but it'll go off for all types
of alert for those counties. If they issue another Amber Alert at 3am
I'm going to turn the d*mned thing off...)

Yep - push pull amps make wonderful frequency multipliers. In the days when there was nothing in use above them, it didnt matter. Now it does.

Andrew VK3BFA.

There is a design for a 2M amp using a single 4CX250B in the old
RSGB VHF/UHF Manual. The inductor in the anode circuit is 3.5 turns
of 1/8 inch copper tube. The output coupling loop is 1 turn.

I don't see any reason why you couldn't make a push-pull
version with a pair of 250Bs.

> The issue of voltage rating of the o/p cap is of course an issue, and the

You can reduce the risk of frying the operator by grounding one
end of the output coupling loop.

> Any obvious reason that this isn't a common approach ?

The only advantage I can see with this arrangment is a reduction
in the size of the amp. Since a 500W tube amp will require a large
power supply, I don't see much point in building a tiny PA.
A stripline amp will give greater efficiency and will only
be a little bit bigger.

4772. Re: High Q caps for 60 Khz loop antenna?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-24 15:26:04 UTC
From: TRABEM <>
Message-ID: <pptpl15nqhg7pogko98vaffrhnld62mdr3@4ax.com>
Source record: 16605

Yes, I'm sure.

It's a 60 foot run to the house, which is relatively short in terms of wavelength.

I am feeding it with a balanced line (actually both conductors floating). So, the pickup by the line to the house should be quite minimal. I've tried 300 ohm twinlead and cat5 twisted wire cable. Both work well.

Would never use anything as crude as coax for something like this, it is just asking for trouble.

Paul, there are no mixers. It's not a superhet. No mixers, no diode detector, no tuned circuit between the antenna and the detector. An active component anywhere between the antenna and the detector defeats the purpose of a quadrature detector...and, since we don't need an rf stage at all, the receiver is much cleaner than conventional superhets ever could hope to be.

Strong signals on adjacent frequencies that force their way into the front end just end up being cancelled out by the quadrature detector (witht he exception of harmonically related signals)...which is another advantage.

The audio is remarkably clean and crisp.

One would NEVER use any sort of a preamp in a quadrature based
receiver.
Regards,

T

The loaded Q (and the circulating current) of the tank will be
necessarily high because of the tube output capacitance. The
efficiency is dependent upon the loaded to unloaded Q ratio. The
tuned line approach can offer higher unloaded Q and a physically
larger structure to dissipate the heat generated by the inevitable
loss.

Output coupling will likely be problematic as well.

I ran a single tube with a wound plate inductor and the efficiency was
pretty low, but it was just a 100W driver so size was more important
than efficiency.

All class C amps make pretty good frequency multipliers. If you're
worried about the -second- harmonic, then p-p is superior.

Not really. That's the way it's usually done (along with a resistor).

Have a look at the ADCH-80A from Mini-Circuits -- it's designed
expressly to bias MMICs. Good to several GHz.

So they are doing that. I saw it coming but never got that far. Mine went off permanently on May 22, 2004, after being awakened twice in three hours for a thunderstorm *watch* (which wasn't important enough to "tone out" at 12:06 AM when it was issued). I was two pages into a letter to my Congresswoman before I found out that the amber alerts soon to come were mandated by Congress.

The web sellers of these things don't make it easy to determine whether their radios allow programming by type of alert. Though one did offer a selection something like normal/priority/emergency, that doesn't help because they'll probably make all the amber alerts emergency status. I'd love to see a list of weather radios by feature that included this information.

Wrap-and-fill polypropylene are a lot better than metalized polyester (mylar
is a trade name for polyester). Mylar also absorbs water and shifts its
Q with time rather badly.

If you care about Q for large values, polypropylene is going to be your
best shot. There are other caps (teflon, and other exotic materials) that
are better, but you also seemed concerned with cost. Higher voltage for the
same value with give a better Q.

Good luck.

Steve.

Greetings. I've only been a ham for a couple years. Not really done anything w/ it however. Just homebrewed a thing or two, but never made any QSO's. I just acquired a 5w 20m rig (all my budget could allow).
Can someone give me any tips on how to know when 20m is open? What time of year or time of day is typically good for 20?
I tried looking over some MUF charts... but its greek to me at this point.
I've tried googling, but unless I know exactly how to phrase my search, I'm coming up empty...

Any pointers would be great.
Thanks

Most of the radios I see have only warning watch and statement.. The Amber alerts come in as watches.. So you can't distinguish between them and normal weather warning.. My Midland model WR-100 has led's for the alert types so I am thinking about taking that voltage to start things off.. But I never thought about the amber alerts.. I know most people around here monitor the repeater around the clock.. I'm not sure how receptive they would be to a repeated amber alert at 2am.

As a **VERY** general rule 20m is open pretty much every day pretty much
all day long and an hour or two into the evening.

(many nights it will stay open considerably later)

Source record: 16622

Thanks to all who responded to my question.

I went back and took a closer look at other editions of the Handbook,
and at Solid State Design for the Radio Amateur (SSDRA).

The Handbooks all seem to suggest that the shunt feedback networks
using a resistor and a cap in series will somehow result in more
negative feedback at lower frequencies. Given that capacitive
reactance varies inversely with freq, I still can't see how this
happens. Tim's message seems to provide one possible explanation, but
I'm kind of surprised that I haven't seen mention of this in the ham
literature.

When SSDRA discusses shunt feedback, (Chapter 8, page 188) they have a
resistor, a blocking cap, and an inductor all in series between the
collector and the base in a common emmiter amp. "The inductor has the
effect of decreasing the feedback at high frequencies, while the 470
ohm resistor is the dominant element at low frequencies." That's easy
to see. But without the inductor (no inductor in the Handbook
presentations) it is hard to see how this works.

Thanks again to all,

Since your top posting...

The series C has enough reactance to be effective to fairly low
frequencies. Consider that the 0.1uf cap seen has reactance of
10ohms around 150Khz thats insignificant compared to the resistor.
If the resistor is 1000 ohm then R=C around 2khz.

What you have to ask is what frequency does the capacitors
reactance become equal to the series resistor? For even a
.1uF cap that's a fairly low frequency. I suspect not recognizing
that detail may be confusing. As you get to very low frequencies
that cap may appear to be insignificant but those frequencies are
very low.

To appreciate that revisit those circuits in question and calculate
the capacitor Xc for 1khz, 10khz 100khz and 1Mhz.

Allison

You can tell where 20M is open world wide by using the NCDXF/IARU beacon
system
See URL:
http://www.ncdxf.org/Beacon/intro.html

Specifically 14.100 MHz
If the morse code is too fast --

see URL:
http://www.ncdxf.org/Beacon/BeaconPrograms.html

For programs that will tell which beacons are transmitting

Be sure your computer clock is accurate to within a fraction of a second --
See URL:
http://www.locutuscodeware.com/swatch.htm
--
CL -- I doubt, therefore I might be !

(15MHz and a little QRP transceiver probably isn't a general coverage receiver but...)

Not that easy here on the East Coast. Pretty reliable when there's daytime on one end or the other or both, but a fair bit of fluctuation.

Tim.

For sale: 1) a complete computer controlled PCB machine, computer software, manual, design software and manuals, all that is needed is a small air compressor. Router bits and drills of misc. sizes. The machine is by T-Tech. Does double sided with a .00008 offset resolution or better. I do not have the thru hole plating, T-Tech works with you on that or rig your own. Numerous support computers, the slowest 800 MHz 2) Icom 706 original, Icom 706 MkII GS, Kenwood 1000 general receiver, Kenwood TS450 (needs audio work) spare 6146 finals, driver 12AT7, O'scope(TV repair 6MHz type), HP counter says 50 MHZ top end, worked to 100Mhz with total accuracy, Kenwood 732A 2m/440 transceiver, HP7475 Plotter up to 18x24 multicolor, Heathkit Station: SB101, SB600, SB200, swr,phone patch, HW160 minus top w/homemade power supply, Two large air caps and roller inductor for unbilt matcher, MFJ dual meter matcher, Kantronics KPC-3 with updated firmware complete APRS station, Several audio I/O PCB 1 working proto for digital modes, 14 Mhz Psk31 transceiver QRP about 5 watts out, MFJ 160-6 matcher , 6 meter 3 ele. beam, 2 meter 4 elem. beam, J-pole, 440 6 element beam home design, Large component collection in 50 bin cases, large SMT collection, proto kits unused, 25 ea. ISD2560 voice chips, 30 2cx250s with sockets-or as a whole about
15kw between 10 meter and 440mhz-(commercial RF shield testing of helicopters). No power supply for it, Multitude of 110:24v 1amp ct. power transformers. Fluke meter, old test equip: RF generator, Heath Gate dip osc with all coils plus 440 coil, numerous meters etc. Web site all documentation/support/financial etc., will sign noncompete agreement. Make offer N5TDE@Gardcircuits.com

Again, the common emitter amplifier gives you 180deg of phase change. If this were to be applied directly to the base of the transistor through only a resistor, you would get direct cancellation at a level determnined by the size of the resistor. The feedback network throws in a phase change proportional to the tangent of the reactance and the resistance part of the network. I think the tangent function for the feedback will look something like:

w(k1) / [k2 + w(k3)]

where w is the radian freq. and k1, k2, and k3 are constants made up of R1, R2, and C. k1 = C(R2)**2 or something like that.

As the freq goes up the phase change gets larger - i.e. it moves the phase difference between the collector and the base away from 180deg., which means less negative feedback. The maximum phase change contribution from the RC network would be 45deg as w gets very, very large (arctan 1 = 45). As the frequency goes down, the phase change contribution from the RC circuit gets to be smaller and smaller which means the feedback moves closer and closer to being 180deg - which means more negative feedback. (as w approaches zero arctan 0 = 0)

This is probably only good for RF frequencies. Say, above 1Mhz. I would have to actually write out the transfer characteristic and graph it to see exactly what happens. Conceptually, it makes sense though.

I have taken the sample test and passed. You only want to perpetuate the
stereotype that CB ops are stupid. All you have proved to me is how stupid
you are.

> I'm totally lost by the suggestion of a disc ceramic.

You shouldn't lump "ceramic cap" into a single group and assume it has one set of characteristics. There are many types of ceramic capacitors, with widely varying characteristics. The four most common groups are:

1. Hi-K. These are made with a class of ceramic having a very high dielectric constant. This results in physically small capacitors which are excellent for many RF applications such as bypassing. Their small physical size results in a high self resonant frequency for a given capacitance. The tradeoff is instability in nearly every other respect. They have a very high temperature coefficient, are sensitive to humidity and physical stress, and the capacitance varies with frequency and applied voltage. A common type is Z5U, which has a specified maximum capacitance change of +22 - 56% over the temperature range of +10 to +85 C.

2. "Temperature stable". These are made with ceramic which has considerably lower dielectric constant than used for the hi-k types. Consequently, they're larger for the same capacitance. Their temperature coefficient is much lower, and they're much less sensitive to other factors. They're good for many general purpose uses such as low- to moderate-Q filters and resonant circuits, coupling, and so forth. Q can be quite good. A common type is X7R, which has a specified maximum capacitance change of +/- 15% over the temperature range of -55 to +125 C.

3. Temperature compensating. These are much larger yet, being made from ceramics with a low and controlled temperature coefficient. They're typically very stable with respect to voltage, frequency, mechanical stress, and humidity. A common type is P2G (N150), which has a

temperature coefficient of -150 +/-30 ppm/C.

4. NPO. (Common type is C0G.) These are made from a sandwich of two temperature compensating types with equal and opposite coefficients. They have excellent Q and are very stable. They're good for use in resonant circuits including oscillator tanks, high-Q filters, and other demanding applications. Q can be very good. A common type is C0G, which has a temperature coefficient of 0 +/-30 ppm/C.

NPO capacitors are substantially larger than "temperture stable" types, and much larger than hi-k types. You won't typically find them in large values.

Unlike 6M beacons which transmit continously on a specific frequency, the NCDXF/IARU Beacon system has 18 beacons around the world transmitting on the same frequency in rotation. Please read URL: http://www.ncdxf.org/Beacon/BeaconSchedule.html

You do not need to copy the beacon ID in Morse code, programs are available to ID the beacon transmitting. The program does not read the code, rather it is time based. That is your computer clock is precisely on time and the beacons are precisely on time also. The program shows a world map and which beacon is currently transmitting

The NCDXF/IARU system is a great propagation aid real time -- world wide.

Further there are beacons systems on 14.100, 18.110, 21.150, 24.930, and 28.200 megaHertz.

Jim: 20M usually has signals readable almost ANY day from 6AM to 7PM from
all over North America and sometimes beyond. Only in the worst propagation
conditions can you not hear any signals.

I suspect one of 3 things if you are asking this question:

1) you don't get on the air enough and listen for signals
2) your antenna is very bad, untuned, or in mineshaft
3) your receiver is almost dead.

Check the band more often, check your antenna and check your receiver.

I want to thank Tom Bruhns for sending me some corrections to my rather outdated information about NPO capacitors. First, they're no longer being made as a sandwich of two ceramic types as I said, but with a single ceramic. Second, they're now available in quite large values -- Tom points out that AVX has them up to 0.1 uF in 1812 SMT size. Finally, here's some information Tom sent from an AVX data sheet that gives some additional quantitative information about the characteristics of these parts:

C0G (NP0) is the most popular formulation of the “temperature-compensating,” EIA Class I ceramic materials. Modern C0G (NP0) formulations contain neodymium, samarium and other rare earth oxides.
C0G (NP0) ceramics offer one of the most stable capacitor dielectrics available. Capacitance change with temperature is 0 ±30ppm/°C which is less than ±0.3% Δ C from -55°C to +125°C. Capacitance drift or hysteresis for C0G (NP0) ceramics is negligible at less than ±0.05% versus up to ±2% for films. Typical capacitance change with life is less than ±0.1% for C0G (NP0), one-fifth that shown by most other dielectrics. C0G (NP0) formulations show no aging characteristics.
The C0G (NP0) formulation usually has a “Q” in excess of 1000 and shows little capacitance or “Q” changes with frequency. Their dielectric absorption is typically less than 0.6% which is similar to mica and most films.

As you can see from the characteristics, modern NPO ceramic capacitors can be used for very demanding applications, and are often the best choice.

Roy Lewallen, W7EL

4823. Problem with soldering gun

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-27 05:09:11 UTC
From: David Thompson <thompson@mindspring.com>
Message-ID: <XhZ7f.712$2y.119@newsread2.news.atl.earthlink.net>
Source record: 16556

My sister bought me a Radio Shack Dual Heat soldering gun (150W/230W). This was to supplement
my 120 watt 45 year old Weller. This after my WW II vintage 120 iron died on me.

My main use was to solder coax connectors. The Gun seems to work Ok on soldering joints in say a SB220 amplifier. But the first thing I noticed is that the tip is much to large to fit into the area where the PL-259 outside allows you to solder that to the shield thru the wholes in the 259. No problem but if you leave the gun on too long the area of the tip gets red hot about 1/2" back from the actual tip.

My old Weller does a better but inadequate job of soldering the 259 shield.

Why does the gun allow the tip to get red hot away from the actual tip. The tip is almost new. I notice its made from a silver metal not copper as with most Weller tips. Radio Shack tells me its made by Weller
and they are not aware of the problem.

bad tip or maybe a bad winding in the gun? any ideas?

Dave K4JRB

Hello,

It may sound funny, but that's why I never used a soldering gun and perhaps never will... My 25W JBC with 0.8 and 1.2 mm tips is quite fine for electronic components and connector soldering.

You should be the one who takes an 18 wheeler to pick up a beer pack. Shouldn't you? Perhaps a Mig welder could do the connector job... Hi! I hope you'll never mount connectors for other Hams without any serious DC and HF shortcut tests.

100W+ soldering irons are pretty good for plumber jobs or for desoldering fast and clean, but definitely not for your aim.

73 de F8BOE Olivier ...-.-

??!!

Well, maybe if Dave's doing BNCs or N connectors then a 100W+ unit is
too big. But "...of soldering the 259 shield.", PL-259s are a
completely different case. I had a 70/140W "dual-power" gun, and it
really wasn't adequate for doing PL-259s.

Managed to find a 200W+ Weller at a Lowe's store in Clarksville, and it
does the trick. You've really GOT to have that heat, a PL-259 shell is
an awfully good heat sink...

>>Why does the gun allow the tip to get red hot away from the actual tip.

Mine doesn't, though it does get hot enough to melt solder a fair
distance from the actual tip. I guess I expected that.

First thing I'd suspect, especially if you're having trouble soldering
PL-259s with a 230W gun, is that the tips aren't making adequate contact
with the secondary of the transformer, the metal tubes coming out of the
handle. At the risk of stating the obvious, those little nuts at the
end of the tubes are good and tight, right?

>tip is almost new. I notice its made from a silver metal not copper
as with most Weller tips.

The tips for mine are silver in color. I guess I figured they were
tinned copper but could be wrong.

A trick demonstrated to me by a friend in New Mexico. (I use "N"'s and it doesn't bother me, but he was putting a 259 on a piece of coax and managed to amaze me.) You use a soldering gun, but with NO tip at all! He pushed the gun sans tip into the ring where the holes for the solder to the braid are, and pulled the trigger. In very little time, the I*I*R losses had the 259 hot enough to melt solder and he flowed it into the braid. Gets the heat into the right place, Give it a try.

Why on earth would anyone want to pass an Amateur test to talk to guys like this is beyond me. At least with CB you can have a laugh and also use it sensibly without having to dedicate your whole life to the bloody thing.... Those people who look down on CB because they are amateurs really...really need to get out and experience some life..... and i dont mean down to the ham rallys to buy some more of someones junk to fill their houses with. Not all Amateurs are like this but theres a lot that are, and a lot of them sit in these newsgroups trying to prove something. Sad old farts....

Guys, electronics technology and densities have changed quite a bit over the past 40 or so years.

My first two soldering tools back in the 1950s were a 100-Watt American Beauty soldering iron, and a Weller Soldering Gun. By around 1965, both were too large and bulky to do precision work on the by then modern electronic, so I purchased a 37-Watt pencil iron (an Ungar Woodburner we called it at that time) which served my needs up to roughly 1989, when I added a miniature, variable temperature soldering iron to my collection which remains in use today.

That original Weller Soldering Gun fell into disuse at least 25 years ago, except for emergency use in panic situation to light cigarettes, although I do take note of the fact that it was very useful for making quick-fix field repairs on the older, low-density, vacuum tube electronics, tinning the ends of power cords, etc.

I continue to use the 100-Watt American Beauty through this day, but only for relatively heavy job like soldering the braid on RG-8U cables to the connectors. Works fine on that application, particularly since its temperature tends to remain rather constant so it doesn't either oxidize most solders or destroy the item that the cable is being attached to.

Arguably, most of the soldering I do today is performed by my temperature controlled iron, generally at temperature settings of 625 or 720 degrees depending on the particular solder that I am using. Once or twice a year do I resort resort to the American Beauty. (It was a gift from my dad back in 1955 and remains in occasional use through this day.)

Even years back, I simply can't remember any soldering iron tip that was pure copper (except for some of those antique iron that you heated on your gas stove). Soldering iron tips are usually plated with an iron coating, and for very good reason. The iron coating slow the pitting and eventual disolution of the tip in molten solder, which in turn extends the life of the tip.

Kindest regards, Harry C.

p.s., I now recall that the earliest Weller Soldering Gun tips were bare copper, which required you to replace them at the rate of about 1 tip per week in regular daily use. Those sold today are iron coated. Still, today I know of no one using Weller Soldering Guns for electronics, however, for the arts and crafts they can be very useful.

And maybe more important, the nuts can be tight but the copper is still
not making good contact. Loosening the nuts and retightening is important
in this case.

I've not bought a tip for mine in thirty years (which means I only bought
them for a couple of years). Someone gave me a yard or so of multi-strand
wire left over from a TV transmitter installation, the punchline being
that each strand was the diameter of the wire used for the soldering
gun tips. I measured the real tip, and used it as a template to cut
the wire to the needed size. It's all worked fine, and the fact
that it's not plated doesn't really matter because the tips don't cost
me a thing. That yard of wire is still supplying the tips.

I find that those who brag about their IQs is about all they have to brag about. I know people with IQs higher then yours who couldn't find their way to the bathroom and back without help, so what does you IQ prove? Nothing.

As far as knowing more about radio, I converted my first transmitter, a Heath DX-60 from controlled carrier AM (you even know what controlled carrier AM is without looking it up?) to high level plate modulation (you even know what high level plate modulation is without looking it up?). I once designed and built my own SSB 80-10 meter transmitter plus many other pieces of ham equipment. Also constructed a 15 meter three element beam using gamma matching (you even know what gamma matching is without looking it up?). What have you designed and built for your 'good buddy ten-fer ther' cb hobby, mister IQ?

That's downright silly. Y'all gotta have time to put the hammer down and
find y'all's selves a convoy and spot them smokeys from the rockin' chair.
Then y'all gotta test y'all's leenyars by ratchet-jawin' "Walk Walk Walk
On Yooooooooooooooo" on channels 6 through 34 simultaneously. (That
means "at the same time".)

4835. VNA and tank circuits?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-27 18:16:44 UTC
From: James Skalski <jskalski@yahoo.com>
Message-ID: <gQ88f.5702$0V6.3968@trndny06>
Source record: 16568

Has anyone used a VNA to set up taps on an amplifier tank circuit or
used one to set up taps on a coil in a transmatch? Maybe a small
capacitor on the anode lead instead of the finals to match capacitance
and then measure from the output of the amplifier with antenna relays in
"on" position. (no other power to the amp :)
I am thinking that the caps can be set to expected mid band capacitance
for each band. Then work on the inductor taps to get the plate impedance.
Or should I just measure the inductor and make the taps based on the
inductance measurement? It seems that if the tank circuit parts were in
place the taps would be more accurate.
I am looking for a tutorial for non engineer types. (tards :))
or a simple explanation. Step by step would be nice.
This is the hard part about making an amp? right? I mean besides the
drilling and metal cutting, and locating parts. Maybe others might be
helped as well by a good explanation.

Two good posts below, HOWEVER...

Guns, in general, should not be used for PL259s -- though W4ZCB's method is a good one. I have used this technique in the past, but don't recallspecificlly on what, just that is was a massive solderiang job. I also have a device, resistance solderer, that designed to do this and is used for doing dental soldering...and now, PL259s. This type of tool puts the full power available into the stuff being soldered. If it is enough to quickly heat the object, then it works.

In its normal mode. a gun puts the power into the whole gun "wire" and this must then transfer heat to the work through conduction - usually via a very small contact point which is an inefficent thermal conveyor. The remaining gun "wire" is accepting the vase bulk of the power and, therefore it is wasted (un-used to heat the work).

Soldering things like PL259 generally requires thermal capacity, not just temperature. "Guns" are not well suited for this work. This is accomplished with a LARGE tip. You need to get in, heat quickly and get out quickly. The large tip allows you to heat, in a shirt time, the _work_, which also has a large thermal mass, without cooling the tip appreciably. To do a good job, you should be able to heat the shell in less than something like 2 seconds, apply solder, let it flow and get out in a total of something line 5-6 seconds.

I think the gun tip-wires turn red-hot, back from the tip, because you are using the PL259 to keep the real "tip" cool and continuing to run the high current through the tip WAY too long. The power needed to maintain the tip's temperature is not enough alone. It is not really the wattage of the heater, but the thermal capacity of the large tip that gives the amount of and rate of heat transfer needed.

73, Steve, K.9,D;C'I

A trick demonstrated to me by a friend in New Mexico. (I use "N"'s and it doesn't bother me, but he was putting a 259 on a piece of coax and managed to amaze me.) You use a soldering gun, but with NO tip at all! He pushed the gun sans tip into the ring where the holes for the solder to the braid are, and pulled the trigger. In very little time, the I*I*R losses had the 259 hot enough to melt solder and he flowed it into the braid. Gets the heat into the right place, Give it a try.

Message-ID: <djr6icjaf1@engnntp2.cig.mot.com>
Source record: 16570

A resistor alone has also been used. I have used a combination of L & R and
L with ferrite beads as well.
While the 500 ohm (10:1) guideline is a good one, teh impedance can drop
well below that before causing trouble.

ALso, the suggestion of the resistor to "dampen" a resonance is valid. You
can take the choke above self resonance this way (self resonant freq can be
in the upper part of your freq range). In the past, chokes were specially
wound to raise the self resonant freq, but for this range, I suspect there
isn't much help there.
73, Steve, K,9.D;C'I

P.S.
Paralleling caps and series'ing inductors is generally frowned upon. If
needed, parallel caps are usually separated by a bead or resistor. I've not
seen series chokes used.

> other power to the amp :)

You bet Jim, ONLY way to do it! Put the tube in the socket, place a 1/4 watt resistor plate to ground of the value of your plate load, stick the VNA on the output port (Refl mode) and tune for maximum return loss. You should readily get 40 dB to 50 dB, log the settings and you're all tuned up. (Don't forget to pull the resistor before you apply power, although if you do, it will remove itself in short order.)

You can measure the caps and place tap on the inductors where you get return loss or measure the inductor and tune the caps for RL. Use the data in the handbook for expected values for the plate load resistance transformation and whether it's a Pi or Pi-L network.

well, the IF image on many 'lesser' general coverage rigs with 455 kc IF
would fall within a pointer width of 14000 so the OP may have been
correct with his statement.

A BFO will heterodyne a signal on *both* sides of the carrier. Most
modern receivers are designed to filter out the heterodyne on one side.
For CW signals, which side depends on the manufacturer. (i.e. there
is no convention!)

> Who decides to which side of the carrier the BFO will
> heterodyne a CW signal.

For many SSB+CW transceivers, the maker of the transceiver decided on a default sideband at manufacture time. Usually USB for rigs that are capable of both sidebands.

For the oldest SSB equipment you don't get a choice of sideband: 14MHz and above comes out on USB, 7MHz and below come out on LSB, due to the 9MHz IF + 5MHz VFO scheme.

> I mean there must be convention, otherwise
> we would have to find out on an individual basis

It doesn't matter as long as you're consistent between your TX and RX, AND you make sure you're inside your band.

With most (all?) modern synthesized transceivers the frequency on the display is that of the CW transmission in CW mode, but on older SSB+CW rigs there was an offset (between a few hundred Hz and a few kHz) between the dial and the actual CW transmission frequency (which was in the sideband - the dial was calibrated to the suppressed carrier frequency in USB/LSB). The offset was usually mentioned in the manual (or in fancier rigs with RIT/XIT could be dialed in).

Tim.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B

licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

>What is Ham Radio?

Do you have some point to prove here you ignorant bandwidth waster?
What kind of asswipe constantly posts the same dribble when in fact
newsgroup articles are archived?

What is Polymath?

He is a self important asshole who's self assumed duty is to educate
folks about that which he knows nothing but only quotes things he has
heard or read. No actual brain activity belongs to PolyDouche.

Why do you constantly keep this up?? You prove you are to newsgroups
the very thing you hate most about others.

Why waste the space on this newsgroup, and why waste the bandwidth???
If you want something to play with stick your hands in your pocket and
play. You are the lowest form of life that exists.

You Polymath are truely worthless, no one here learns from your constant
post of the same dribble and in fact no self respectable ham would act
in the way you do, proving you are among the most childish of the very
CB'ers you seem to hate.

Suck me, blow us, or just blow away!! Fuck your useless posts!!!
Go talk politics with the WalMartians at your local WalMart.

Do you have nothing better to do than post the same worthless note?
Are you that lonely and disfunctional? You don't even rate as high
on the evolutionary scale as the idiots of 3898khz.

You have made a name for yourself indeed Polymath the biggest asshole
known to any newsgroup.

Tell us of anything electronic or ham related that you ever built. Give
us something of value. You can't and you know it and it pisses you off
to look at such a worthless asshole in the mirror each and every morning
and the worst part is tomorrow isn't looking any better.

Take your worthless post, print ten thousand copies and shove one up
your ass each morning while you contemplate your own suicide. If you
lack the methods and means to such an end I'll be the first in line to
by you a complete suicide do-it-yourself kit.

Opinions expressed here are my own but reflected by the entire newgroup
and anyone else with 2 or more functioning brain cells.

Piss off pal and take your idiotic plagerised post with you.

take a look at the new crop of 1W LED flashlights that are on the
market. A lot of very white light from these modules. No need to
bother with trying t get intensity, something like 8 hours off 3 AAA
batteries.

4867. Re: BFO, CW, sideband question

Date: 2005-10-29 03:49:25 UTC
From: Jaggy Taggy <outhouse@midcoast.com>
Message-ID: <BF88698C.BDE6%outhouse@midcoast.com>
Source record: 16500

I started this thread because there is a bit of confusion in my head
regarding where the signal is, where the carrier is and what is indicated on
my radio dial.

And by the way, I do have an older radio, a Kenwood TS 830, not a modern
radio. My radio-display shifts on transmit to a frequency 800 Hz higher than
what was displayed on receive.

So I assume it displays the carrier frequency on transmit, while on receive
it displays the heterodyned frequency, which on my radio happens to be
lower, but as some indicated in this group, this is an arbitrary choice made
by the people at Kenwood.

The ARRL CW transmissions frequencies, for example, seem to be given for the
carrier which is not what my radio displays (my radio displays 800HZ lower
on receive) and therefore I need to adjust my radio to a different frequency
than what is advertised.

This is confusing to me.

It is also confusing me that I can't receive SSB on the lower bands using
USB (and a slight retune), I need to use LSB.
I don't know why since I learned that the two sidebands contain the same
info.

And the more I think about it the more I realize that I don't really
understand this whole topic very well...

Uwe

The 'true' CW frequency would be that of zero-beat as opposed to where
you 'hear' the signal. The rig assumes that you are listening to a beat
note offset by about 800 Hz and compensates accordingly on transmit.

Alas, a SSB station is only transmitting one of the sidebands! This by
convention is LSB on 40 and below and USB on 20 or above. If a station
WERE to xmt USB on 75 meters, for instance, you would have to use the
USB position and would not be able to detect it in LSB.

In a public and international discussion group, it is
ALWAYS open for others to publish their own FAQs.

That they do not and merely resort to the abusive
behaviour proscribed in my FAQ suggests that my FAQ
is correct.

In addition, if you disagree with what I post, and do
not wish to see it, then it is a simple matter for you
to resort to use of your kill-file. Responding in the
rather silly and infantile manner in which you did
makes you seem to contribute in the very manner which
you would otherwise proscribe.

If you have a reasonable - and reasoned - response as
to what you think Ham Radio is, or is not, then publish it
here. That is, indeed, what an international forum such as
this is all about.

You would seem to be one of the Childish Broadcasters (CBers)
warned against in the article.

Shame on you.

Stupid boy.

Why, so that you can abuse people behind their back? What would be the point
of replying to someone, but cutting out the group that the OP uses?

> In respect of that, I apologise if my remarks have caused
> any offence to the CB community.

I would bet that, if this was cross-posted to *real" tech groups, many qualified
engineers would also be offended by your suggestion that you are a "higher"
level of person.

> However, I do not withdraw my
> remarks - they are my opinion as to the relative
> standing of Radio Hams and of CB Radio
> enthusiasts where the playing-field is that of Radio
> Hams.

Playing field? So this is nothing more than a game to you, see who can cause the
most offence.

Your problem is that you are blaming the wrong people.
Maybe this is all just an excuse, a cover for your hatred of CB, nothing to do with
Amateur rules. Otherwise you would direct your comments and anger at those
making the changes.

> However, having said that, the material quoted below
> serves, I think, to illustrate quite well the
> intellectual standing of CB Radio enthusiasts
> upon which I have commented.....

You write a message which anyone of at least average intelligence will know will offend
certain groups of people, then pretend to be shocked when some respond angrily. You
may be a Ham, but that doesn't mean you can act.

Before putting the angry response down to "CB mentality", take a look through the Google
archives at all the serious abuse sent to newsgroups by some licensed Amateurs.
Six of one, half a dozen of the other.

Regards,

Peter.

NO...
It IS your intention to insult them, just behind their backs so you run less risk of them replying. Your post was not really intended as an "FAQ", it was purely a relatively "safe" release for your personal anger.

Wuss.

> CBers have the right to besport their habits in the
> appropriate place as do all the lower classes, which
> in this context is rrcb (and urrcb).

If you must start seeing this as a class system, look up "Amateur" in a dictionary. Please consider the meaning of the word before suggesting that an "Amateur" is above the professionals who design and build equipment to the standards set by Governments, standards far above that required by an *amateur* producing equipment for his own personal use.

> > >the aforementioned category are not Radio Hams by any stretch

> > >of the imagination!

Comparing, as you call them, "disgraceful Class Ber's" to 6 year old children is clearly intended to insult people.

Please think before displaying such ignorance and stupidity by blaming CBers for the rules...
they have absolutely NO CONTROL over such matters. CBers neither set the rules nor claim to represent "members", that woukld be Ofcom and the RSGB.

CBers do NOT see Amateur and CB as "sisters", it is people like the RSGB, the RA and Ofcom and
a certain magazine publisher who see it that way and make decisions to mix, combine and change
rules and formats.
Any sensible CBer would prefer to keep Amateur and CB separate, as they are separate services
for totally different purposes.

If you must get so angry, do yourself a couple of favours...
1. Blame and whine at the correct people, those able to make the changes.
2. Watch your blood pressure, OM.

I agree with keeping the Amateur requirements higher. I agree that it is now too simple, and has been for some years. I believe that Amateur radio should be for those with a real interest in radio, and tests should be set to allow those people through - not to get the licence figures up.
But it's pointless blaming people for taking what is on offer, sitting the test required to get their licence.

Regards,

Peter.

> info.

Ah. What you learned about was DSB, not SSB.

In a regular AM (Dual Sideband) transmission the two sidebands indeed
contain the same info and you can tune either one. (or in most cases, both)

But what hams use is SSB, Single Sideband. One of the two sidebands is
filtered out, only one is transmitted.

It is traditional for amateurs to transmit the lower sideband below
10MHz and the upper sideband above 10MHz. Hence, you need to use LSB to
receive SSB signals on the low bands -- the upper sideband simply
doesn't exist on these signals. And vice-versa on the higher bands.

Right Bill, but why. Could I not retune my receiver so that I would catch
the transmitted sideband with my "LSB window"?

I guess from experience the answer is no, and that is also what you said,
but what is the reason??

There is no abuse intended in the identification of Ham
Radio and CB Radio as being disparate activities.

I do not hate CB, just as I do not hate other activities
which are as equally irrelevant to Ham Radio - needlework,
gardening, football, and the M3/CB Fools' Licence scheme.

Visualize a LSB signal as having the carrier frequency at 7000 kcs (or more precisely, phantom carrier). The audio sidebands tune down to 6997. A USB signal on the same freq has the audio sidebands from 7000 to 7003.

To tune to an SSB signal (and have it intelligible) you have to tune to the phantom carrier freq. You can't fool the rcvr by going 3kc hi or low and switching sidebands. Yes, the signal is there - to wit you can hear it - but you can't detect it.

Why? Think about how BFO injection works. Take a fixed freq BFO of 7000 in this case for simplicity. 7000 beating against an USB audio sideband at 7001 gives you a bit of 1 kc audio information. Repeat the same with an audio sideband at 7002...you get the 2kc audio information. If you try to fool the radio by tuning to 7003 and selecting LSB, yes you have duplicated the bandpass from 7003-7000 but all that audio information is now inverted.

In most rigs nowadays there's a single filter of about 2-3kc width that is used for both sidebands. When you select USB or LSB you're simply moving the bfo freq from one edge to the other.

Thats all an oversimplification but does it make sense?

-Bill

Hi!
Just to make things more complex (or simple). When you tune from LSB to USB you also change the frequency of BFO, putting it on one side or another of the IF filter. If you listen to LSB on USB position you can put the simulated carrier frequency on the right place, but signal is out of IF passband.
Sorry for my bad English. Hope you understand.

Some interesting details about 'Polymouth'

http://tinyurl.com/cdudd

http://tinyurl.com/5mcwk

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to

be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B
licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

Notham Hull is second only to Brian Reay in obsession
with me (and therefore in envy of me by Brian Reay's
arguments) that he resorts to a Japanese ISP to
get round kill files.

What it is to be AN INCURABLE CBER!

Both gentlmen were dismal failures in that they were
either too lazy or too stupid, or both, to be able
to tackle and then pass a 12WPM Morse Test that
otherwise-unqualified self-taught 14-year-olds
were taking in their stride.

Too late - neither will ever be known as a "Class A"
licensee no matter how much they might preen themselves
on being "Full" licensees.

Failures both, and both on international public record as such!

Actually, I think the convention is LSB below 9 MHz and USB above 9 MHz. That comes from the fact that most old rigs used 9 MHz as the I.F. Doesn't really matter though since our voice bands are 40M and 20M (CW only on 30M), so by convention, we use LSB on 40M and below and USB on 20M and above. However, one can reverse this if one desires. It will just confuse new people when they try to tune you in and wonder why they can't get you tuned in...

Modern radios such as the FT1000MP Mk V automatically change the internal local oscillator frequencies so that USB, LSB and CW appear on the same indicated signal frequency, which is what we want. In CW we get a certain pitch frequency such as 500 Hz (not zero beat) at the signal frequency. The value of this pitch frequency can be changed from the front panel by the operator to suit his preference.

In my homebrew rcvr I use the CW USB setting only. As I tune up the band I hear the high pitch of a signal first and it then decreases pitch as I continue to tune up the band (my preference). I use a single xtal filter frequency for USB/LSB and a single xtal filter frequency for CW. The BFO xtal frequency and the VFO frequency counter digital readout (not the actual VFO frequency itself) are automatically changed to their correct values in LSB, CW or USB mode. In CW mode I then have a 500 Hz beat note, which is what I want, not zero beat, and the CW BFO xtal is then the correct value for CW USB.

For a brief description of my homebrew rcvr see QRZ.COM, W0IYH.

Yeah, and more than once I've scratched my head about what type of voice encryption someone was using in the middle of 20 meters before it dawned on me to try listening on LSB<grin>!

The 10MHz figure is somewhat arbitrary since indeed there are no amateur voice frequencies between 7.3 and 14.1MHz - and commercial services don't follow our LSB/USB convention.

As I understood it, the decision to use different sidebands in the two spectrum areas came from the design of some early SSB equipment. If you used a 9MHz IF and a 5.0-5.5MHz VFO, you could cover both 80 and 20 meters without having to mess with heterodyne oscillators. But since you'd be using addition on 20 vs. subtraction on 80, the sidebands would flip.

(there's GOT to be a better way to say that but it's too darned early in the morning!)

At the time either there wasn't a phone band yet on 40 or phone privileges there were very new & SSBers didn't care that much about it. 15 was also very new or non-existant, and I suspect most SSBers didn't believe anyone had a receiver stable enough to receive SSB on 28MHz!

No, not all chicken banders are law breakers, but a very large portion are.

If Dr IQ is running an external linear he certainly is. If he is going
to build a cb transmitter, which will not be type accepted and put it on
the air he certainly will be.

Type approved.... hmm, its a bit of a strange one that ... which makes me
think "type approved" for Amateur is something home made from bits of
anything.... not tested by anyone... just soldered together by an Amateur so
it must be perfect ...right? No spurious emmisions or any interference
because the person cobbling it together is an Amateur..... Now no
disrespect here is aimed at Amateurs, just some of the laws governing the
hobby seem to be crazy. Amateurs building their own kit and having it tested
via some professional body before use i can accept.... but does that ticket
mean you can build your own "boots" and use it no matter how bad it may be
made? It seems so..... sod type approval eh. Or were you just relating to
"licence conditions"
I know a few Amateurs who are law breakers too. Using their illegally
adapted Amateur equipment to listen in to CB frequencies i believe is a NO
NO, unless you have a CB licence... to which would Amateurs actually bother
to get a CB licence? Are the radios actually legal to use on the CB bands??
i dont know 100% so i ask the question. We all do things from time to time
that are deemed illegal.... so your statement on "No, not all chicken
banders are law breakers, but a very large portion are" could be said
against any group of people.

Whats your opinion on M3's? Do you encorage them or see them as a stain on
Amateur radio? Im just curious by the way.

Regards,
Graham

Also known as the M3/CB Fools' Licence - any 6 year old, having
no previous knowledge or experience of Ham Radio can attend a
weekend course and leave on the Monday with a licence.

The scheme is a complete joke and held in widespread
derision by any self-respecting _REAL_ Brit Radio Ham.

No 6 year old has the mathematical toolset to deal with
even the most simple of algebraic transpositions that are
necessary to deal with problems involvng Ohm's Law.

The M3 is a CB licence, nothing more, nothing less.

It's purpose is to fill the coffers of a Brit publishing
company, the RSCB - The Radio Society for Citizen's Band.

Maybe the rules are different where you are, but in the US amateurs can
construct any of their equipment, but it *is their responsibility* to
test it and make sure it operates legally. If it doesn't they can be
held accountable by the FCC. Granted, there are few today, due to lack
of technical knowledge that can do that. It wasn't that long ago
however, that finding a ham station completely constructed by the

amateur wasn't uncommon or often surplus military gear would be modified
for use on the amateur bands. With the plug-and-talk equipment of today,
easier test with given answers that can be memorized, the technical
expertise of the amateur is sadly lacking

> I know a few Amateurs who are law breakers too. Using their illegally
> adapted Amateur equipment to listen in to CB frequencies i believe is a NO
> NO, unless you have a CB licence...

In the US any ham or anyone else can legally listen in on cb frequencies.

> to which would Amateurs actually bother
> to get a CB licence?

Since there is no requirement here for a cb license I don't suppose any
amateur would bother.

> Are the radios actually legal to use on the CB bands??

Only radios that are type accepted for cb use are legal to use on the cb
bands. There is a problem here with imported radios that have 'expanded'
channels that will also operate on the 10 meter ham band. These radios
are not 'type certified' for cb use and they are purchased by unlicensed
persons and are often used on the 10 meter band. Some time back it was a
popular thing for amateurs to take cb radios and convert them for use on
the 10 meter band, just change the crystals, peak up the circuits and
you had a nice little mobile 10 meter radio. Once modified as such the
radios were no longer type certified nor legal for cb use but perfectly
legal for amateur use.

> that are deemed illegal.... so your statement on "No, not all chicken
> banders are law breakers, but a very large portion are" could be said
> against any group of people.

True, but there is a much larger percentage of illegal operation on the
cb band than on the amateur bands, at least here in the US. And we have
the 'freebanders' who for some strange reason think they have the right
to operate on the frequencies between the upper end of the cb band and
the lower end of 10 meters plus just about anywhere else they chose.
>

I must confess I haven't acquainted myself with M3's. Is this a test
free amateur license?

Ive seen a few of the ex military gear on my frequent walks around the radio
rally meetings held in the UK at various times of the year. Ive even seen
small tanks for sale :o)

Indeed. But what i was getting at was Amateur radios that can access the CB
bands not CB's themselves. I know in the UK if an amateur wants to converse
on the 27MHz CB band he needs a CB licence.. his Amateur licence doesnt
cover him/her for it. (or whether thats just M3 im not sure) Im sure someone
will let us know.

In the UK its a simple test (which only an idiot would fail) to get people started on the Amateur bands. I think the main frequencies being 2m. Im not sure where else they can go but its limited compaired to a full amateur and the powers less. Most UK Amateurs are horrified that their airspace is being invaded by these "CB type lowlife" (their words not mine) which suprises me as i firmly believe anyone gaining their M3 licence would go on to Intermediate... etc not stop there so i cant see why the "old hams" arent encoraging them rather than belittling them.

There are all sorts of kit vendors out there. www.qrqrci.org has quite an extensive list. But I would agree with Lector, if the price of the Elecraft doesn't scare you off, it is a really great radio ... any one of them.

Notice that they are really for different users. The KX1 is designed to be "trail-friendly". By that they mean not only small and light, but convenient if you are sitting on a log. The K1 is a nice portable rig, and with the internal tuner and batteries, it is a great hotel-room or picnic table rig. The K2 is more of a base rig, although lots and lots of folks use them portable. To many people, the K2 is the "ultimate" rig.

Jim

20 meters is mostly a daytime band, especially now that we are near the bottom of the sunspot cycle. What that means, though, is daylight at midpath, and on 20, paths tend to be long (even for QRP). So if the sun is overhead say, 500 miles from you, there is a decent chance of hearing something.

Depending on how far up in 9-land you are, 20 may close fairly early. However, up here in the frozen north, there is often over the pole propagation that seems to open up an hour or two after the band "closes".

If you listen during the day, you will hear the signals shift from the east to the west with the sun. When all you can hear is California, the band will probably be closing soon. But then again, depending on all sorts of vagaries, it may soon be time to listen for Hawaii, Japan or Australia.

Don't be afraid to make a call. On 20 CW, 5 watts is more than enough. 20 is a fairly quiet band, and QRP signals don't get absorbed the way they do on the lower frequencies. Once I tried a contest at a half a watt, and my QSO rates were barely different than at 5 which in turn really weren't noticably different than 100. They did fall off as I started to approach a tenth, though. This is with a dipole at about 30 feet - nothing fancy.

Early morning is nice for Europe. Midday the states. Sunset look for South America.

If you keep an eye on the propagation numbers, here are a few clues. The "flux" as it applies to 20 really has to do with how CLOSE you can talk. You will find that contacts closer than about 500 miles are tough on 20 unless the flux is high. A high flux might also help 20 stay open a little longer after the sun sets. The K index jumping tends to indicate that we have taken a hit from a burp the sun has made. An intial rapid rise will mean the bands will be very noisy for a short while, but in an hour or two propagation will suddenly get very good for a little while. Then, a few days later, we -might- get hit with the follow on, which will essentially shut things down for a day. Whether we get hit depends on the exact place on the sun that burped. The initial radiation blast travels very quickly to earth, and the matter that follows takes a lot longer. Thats why the multi-day delay. The initial radiation blast causes the earth's magnetic field to rock and roll for a few hours, which is why the noise. When it settles down, though, the ionosphere is ionized as if the flux were high. Then when the matter reaches earth (if it does) it will badly distort the magnetic field for a day or sometimes more, making for very bad conditions.

If you can find some writings by Paul Harden, read them. This guy has lots
of great stuff on propagation.

Greetings All...

A couple of weeks ago I posted a request for help for a schematic for an Astron power supply. I got over 20 responses...!

Thanks to all!

I also thought I'd tell everyone of the great service I got from Communications Concepts in Beaverton, Ohio, when I was looking for the part I needed to fix the supply. They were quick to answer my e-mail, and when I ordered the part, it was here in two days via priority mail. They also didn't try to whack me with "minimum order" stuff.

Thanks again....

Yes, one would think so. That is what our Novice license was for, an entry type of license, nothing real hard on the test, only 5wpm for code, limited power and not all frequency privileges.

> so i cant see why the "old hams" arent
> encoraging them rather than belittling them.

It seems that is often the position taken not by just 'old hams' today, but by some of those who do upgrade. Kinda like how as a freshman in high-school you were looked down on by upper-classmen. It didn't use to be that way. When I had my Novice ticket, I probably worked more General and higher class licensees on the Novice bands because they would come to the Novice frequencies and work us, sending code slowly and carefully to encourage us to get proficient enough to upgrade. Amateur radio used to be very gentlemanly, still is for the most part but seems amateur radio has begun to reflect much of today's rude society.

"Not-Ham" Hull is otherwise known as "THE INCURABLE CBER",
one of the CBers-Masquerading-As-Radio-Hams who infest this NG.

Some years ago he was abusing his employer's computer system
to heap offensive and insulting remarks at me, an abuse to
which I took exception and complained. Not-Ham has proved himself
to be infantile in the extreme by maintaining a temper-tantrum
on the matter for years on end. If only he could see that
I saved him from himself......in today's world, such abuse
of an employer's computer system is a sacking offence!

But then, that's the brain of a Childish Broadcaster (CBer)
for you!

I seem to remember I was castigating you for your god-awful remarks re the deathd of the Soham girls, so totally justified. Luckily, your email (pleading for me to be sacked), was laughed out of IT. You were spotted like the insane fool you are, in about 10 seconds.

Remember, dear readers, that only one person on the entire newsgroup, has ever been arrested for internet harrassment. I bet you can't think who that might be...

Draw your own conclusions.

4931. Re: BFO, CW, sideband question

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-10-30 12:44:04 UTC
From: Scott <acepilot@bloomer.net>
Message-ID: <2YudneP3CMRKIvneRVn-iQ@bright.net>
Source record: 16464

Yup, you've got it!

Now for the $64,000 question (which will only buy about 21,000 gallons of gas these days!)...With these modern rigs, if I want to answer someone calling CQ on CW, how do I adjust my radio to be on exactly the same frequency as they are calling on (to conserve spectrum for other operators)??? My "old" TS-520 has a "Tune" position, which sets the bfo frequency exactly to the I.F. frequency (I don't have the service manual in front of me, but follow the logic here). As I tune the radio (with the VFO) in this TUNE position, when I have the VFO set to provide zero beat, I will be right on his frequency since my BFO is running at the I.F. frequency (9 MHz) and the combination of the far end transmitter frequency and MY VFO frequency gives an I.F. output at 9 Mhz, so the difference in frequency is zero. Whent I then return my switch from the "Tune" position to the CW position, it shifts the BFO 800 Hz in SOME direction (up or down, I can't remember and I don't really care!). Now his signal mixed with my VFO and my now shifted BFO (which is now running at 9.0008 MHz, for example) provides a tone of 800 Hz. Easy!

My "new" TS-690S doesn't have a TUNE position. The manual says to tune for a tone frequency of 800 Hz (or whatever you have the "CW Tone" frequency programmed into the radio). My question is how the $#@% do I know when I have an 800 Hz tone coming out of my radio? Do they really expect me to have a freq. counter hooked up to the speaker? I have overcome this by setting the RIT to display either 800 Hz up or down (can't remember which right now), turn on the RIT, zero beat they guy, turn off the RIT and then I will be on his frequency. I find it's easier to CALL CQ and let the other guy worry about getting on MY frequency ;)

Polymath,

Just thought I would let you know, since almost all your replies come from the CB crowd, that at least on this side of the pond, someone agrees with you. The continuing "dumbing down" of license requirements will be the death of Ham Radio. Unfortunatley, it's a side effect of the overall dumbing down of the entire educational system. Teachers are not allowed to flunk a student, or even criticize, for fear that the poor student's "self esteem" will suffer. If a student makes a gross error, the response is, "I can see where you get your answer, and it is very good, how about considering some alternatives?" Instead of, "Sorry, you're wrong, go read the f*cking book!"

Keep it up, don't let the ignorant bastard get you down.

John W2AGN (unlike most of your gutless responders, not afraid to identify myself)

Newer rigs tie the sidetone to the offset, so that if you zero-beat the sidetone with received signals you're transmitting on the same frequency as the other guy. In most rigs if you close the key without putting the rig in transmit (i.e., break-in is off) you'll get a sidetone without muting the receiver, allowing you to zero-beat the sidetone.

Older rigs often had a "SPOT" button which keyed up low-power transmitter stages to allow you to zero-beat the transmitter against received signals. My FT1000MP also has such a button - I'm sure the electronics behind it are very different but its purpose and function are the same as in the old rigs.

To be honest I don't worry about it. After 30 years of CW operating I'm pretty good at getting it right!

The sidetone you hear when you key down is going to be pretty close
to the 800Hz offset you need. So just tune the other guy until he
sounds roughly the same note.

> Do they really
> expect me to have a freq. counter hooked up to the speaker?

Gees, give guys a 8-digit frequency counter and they think they
have to be tuned to 1Hz to work somebody else. Most of my rigs
had more than 800Hz of chirp when I bought them :-).

Tim.

John,

Thank-you for your kind words. It must be difficult,
however to navigate through the QRM of false Polymaths
who are infesting this NG. (I note that a rather silly
and infantile CBer has already replied to you as Polymath)

For some reason, despite taking a stance of encouraging
all comers to exert themselves and join in what is an
exciting technical pursuit, I am plagued with quite
a few mental defectives who forge postings, amongst other
things. I really do not understand the infantile mentality
of them, for, if they were to put the same effort into
pursuing Ham Radio that they do into their childish attacks,
they'd find life much more rewarding!

There was something from you in my in-tray, however
I delete all unsolicited emails - if something comes
up as the result of the NG then the place to discuss
it is in the NG.

Thanks again and 73.

Source record: 16473

Tim: Thanks again for your help, and thanks again to all the others
who've replied to my question.

I see what you are saying. I reached back to Terman's description of
these kinds of feedback netwoks in tube circuits. I think he describes
just what you are presenting (but I think your presentation is
clearer!)

Obviously I'm still struggling with some very basic amplifier issues.
Am I correct in thinking that shunt feedback would have a number of
different advantages in a common emitter transistor amp? Looks to me
like the feedback network would give the designer the chance to:
1). Manipulate the input and output impedances
2). Counteract the tendency of the amp to "take off" becasue of the
rising gain characteristic (as frequency is lowered).
3). Reduce any distortion (IMD) generated in the amplifier itself.

I'm most shaky on #3. Am I correct in thinking that if you have some
sort of spur or IMD product generated in the amp itelf (say in the
collector circuit)the negative feedback provided by the shunt tends to
nock some (most? all?) of this distortion down?

Thanks, 73

#3)
Negative feedback of any kind then to make a circuit with nonlinear
action (however small it may be) more linear. IMD (InterModulation
Distortion) is a mixing action from nolinearity that occurs when two
signals are passing through an amplifier that has distortion, less
distortion, less IMD.

Looking for a source of permeability tuned inductors.

Don't know wether these are still manufactured these days.
25 years ago most high end VFO's (or PTO's) had these inductors, eg Collins,
Drake etc.
Also heavily used in construction of analog car radio's.

Regards,

Paul van Dam, PA7UL

For 'high power' soldering , I use a butane (cigarette lighter) gas
soldering iron with kathalytic burner.
Temperature can be adjusted by changing gas flowrate .
I use an iron made in Ireland ,make Portasol .High power tip/burner can do
up to 100 watts which is more than adequate to solder (PL259) plugs. Also
very suitable to make small enclosures from scrap printed circuit board
Very handy also for outdoor use .....since the tool is self-contained.
Nowadays there are a number of makes to choose from.
I would never use an electric soldering gun.

4946. Defibrillator caps for ham use?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-01 01:12:56 UTC
From: James Skalski <jskalski@yahoo.com>
Message-ID: <siz9f.5733$cg6.5357@trndny04>

Has anyone use a oil filled cap from a debrillator for a high voltage amplifier? What are the differences in this cap?

Bill,

Negative feedback can be used to help fix input and output impedances. You have to be careful with shunt type negative feedback to make sure you don't have any regions where the phase change becomes 0deg. This can happen when you have both capacitive and inductive reactances in the circuit. That is one reason parasitic oscillations happen at very high frequencies. Even connecting wires on resistors can look like inductors at very high frequencies.

As far as negative feedback having an impact on distortion, you must be very careful to identify what kinds of distortion you are speaking of and have a

good feel for what the feedback networks are doing. Negative feedback, improperly designed, can cause audio amplifiers to not be "flat" across the audio spectrum. This can be considered to be distortion.

Negative feedback, improperly applied can cause gain compression, e.g. in an RF Linear Amplifier, which distorts the dynamic range of the applied modulation causing a distortion which impacts intelligibility.

IMD distortion is typically caused by a non-linear device. Since a transistor is an inherently non-linear device (it is based on "diode" junctions) at low voltage levels since it acts like an on-off switch, there will always be some level of IMD that negative feedback won't help.

Where negative feedback *can* help is in keeping a Class A amplifier operating in the Class A region. This will minimize IMD. If you get an amplifier out of the Class A region, there is bound to be some IMD. If you are running a Class B amplifier in push-pull this is a "psuedo" Class A amplifier and negative feedback that would keep each amplifer right at cutoff for the negative part of the input would help minimize IMD distortion. If you are running a Class C amplifier, negative feedback won't help much because you are running a non-linear amplifer to begin with.

Hope this helps.

HamPoll is here in order to give amateurs a chance to speak for themselves, and in time to provide reasonably accurate and significant polling data on a variety of issues related to the amateur radio service.

You are welcome to browse the polling data we have, but we especially encourage US amateurs visiting here to register with thier callsign and vote in the HamPoll Polling Station.

Whether you come to browse, to discuss or submit new polls, or to tender your vote, be sure to visit regularly as new polls are included from time to time, and the poll data changes as more hams participate day to day.

Stop by at: http://www.hampoll.com

>I would never use an electric soldering gun.

Neither would I. A normal small iron can be used for soldering large
objects, if they are pre-heated with a hot-air ("paint stripper") gun.

To solder a PL259, for example, pre-heat the plug body with the gun
until it's good and hot, but still some way below the melting point of
solder. Then put the gun down, and switch to your regular 25/45W iron
for the actual soldering. The solder will now melt quickly and easily.

Try it - it's so much easier than using a monster iron or an electric
soldering gun.

>Jim n2go

Defibrillator caps are only rated for energy storage, and are not designed or rated to handle AC ripple current. Voltage ratings of defib or photoflash capacitors are likely to be given as "...kVP" and there will be no ripple current marking.

AG6K gives further information on his website:
http://www.somis.org/D-amplifiers3.html

Follow Rich's recommendation: test the capacitor first with low-voltage alternating current, and if it doesn't get warm, operate it substantially below the maximum voltage rating. However, my own experience has been that such "kVP-rated" capacitors may work fine for a few years and then suddenly fail short-circuit. I've lost two that way, and wouldn't use them any more.

I have used a MFJ259 antenna analyser to set up amplifier tank circuits,
with the valves (tubes) left in place (but obviously without any power
applied to the unit)
Also antenna matching units (I prefer NOT to use the word 'tuner') can be
set-up very easily with the above instrument.
I consider the MFJ259 an excellent instrument for radio 'amateurs' ,
suitable for lots of applications.

Do you think people would like to have a DDS VFO whose frequency and phase were both direcly related to a common time/frequency standard like WWV? That is, two people anywhere in the world using the VFO could make a signal having exactly the same phase as measured at the transmitter. I would adjust for lightspeed lag using a GPS receiver.

I am thinking this could be useful for coherent CW work.

Opinions?

Well, no existing communication standards require independent phase coherence between transmitter and receiver, for the simple reason that the path length is randomly fluctuating (and there is also multipath).

As an example, if it's 3000 miles from me to you, the actual path for HF communications is going to be somewhere between 3100 miles (a single bounce) and 3300 miles (several bounces and a little sideways jog) or more. With wavelengths like 20meters or 40meters, that 200 miles represents many many wavelengths.

Tim.

Very good Ian.. I shold have remembered this. A good way to solder ceramic substrated PA modules, as well. I have a hot plate.

However, with the PL259, you may have an issue with the coax dielectric melting. That's why I recommended teh high heat capacity, get-in-and-get-out process. Or the PL259 dielectric. I see mostly cheapies selling @ hamfests - Teflon's OK, though, no?.

4963. Battery PS for Shack

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-03 20:51:58 UTC
From: amarcpassy@gmail.com
Message-ID: <1131051118.795396.271760@g14g2000cwa.googlegroups.com>
Source record: 16495

I'm building a PS for my shack, and the receive only current draw of all of my equipment is in the 2A range. QST a few years ago had a great charger/battery circuit where the PS/charger generated up to 500ma and, depending on the voltage state of the battery (he used a SLA) would apply the charger voltage, limited to 500 ma (minus anything used for running equipment, about 220 ma max for him) to the attached battery in an increasing duty cycle as battery voltage went down. When he transmitted, his load was about 2A, and it would come out of the battery.

I'd like to do something similar, but larger. I'd like to build a charger/PS capable of supplying about 3A max, and use a deep-cycle marine battery as a reserve supply. Are there any circuits out there that allow a battery charger to run on a battery that can possibly be operating?

Thanks.

Marc

If you already have a GPS receiver, you can lock to their time code -- this is already commonly done in, e.g., cell phone base stations to keep everyone in sync as you move between cell sites. It's also a popular way to get a cheap, high precision 10MHz reference clock for spectrum analyzers and other lab gear -- TAPR has an inexpensive board that does this.

I think you may have the wrong impression of this. It isn't the same as using hot air or a hotplate to do the actual soldering.

In this case you're only using the hot-air gun to give the connector body a moderate temperature boost of maybe 100-150C. It's still the iron that melts the solder - the difference being that you can now use your regular 25/45W iron.

The worst that happens with solid polyethylene dielectric is that it softens; but then it hardens again. If the coax dielectric melts and runs, you've heated the whole thing way too much, and for way too long.

The dielectric inside the plug is even less of a problem. If it doesn't melt when you solder the center pin, it will also handle moderate heating of the connector body.

So in practice there aren't any problems.

4966. Re: Battery quality/life/efficiency/MostBangForTheBuck/whatever

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-04 00:08:56 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <11ml9kr9dfi6dce@corp.supernews.com>
Source record: 16399

The problem with making comparisons is that the power you can get out of most types of primary (non-rechargeable) cells depends heavily on a lot of factors, such as:

-- Current drain
-- Duty cycle
-- Temperature
-- End voltage

In addition, some devices such as many GPS receivers have switching regulators, which drain the battery at a near constant power rate. Others drain at a nearly constant current rate, and still others with more like a resistive load. Each type of cell behaves differently under each condition.

Only a few rules of thumb can be put forth:

1. For heavy drain applications such as photoflash or an HT, alkalines last many times longer than "heavy duty" carbon-zinc types, so the latter is seldom an economical choice for those applications. Likewise for applications with moderate but constant drain such as a GPS receiver. Carbon-zinc is probably more economical (unless you use alkalines from Costco or other discount store) for light-drain, intermittent use such as a radio. Flashlights aren't light drain, but do fairly well with carbon-zinc if used only occasionally. But I don't use carbon-zinc for anything.

2. You're unlikely to see cell life increase anywhere near in proportion to cost by using "titanium" or other "premium" alkaline cells -- their special characteristics are mostly created in the marketing department. If in doubt, consult the manufacturer's data sheet, readily available on the web.

3. Modern NiMH cells have about the same capacity as alkaline cells -- more at very high currents --, and the capacity is quite constant over a wide range of discharge conditions. A down side is the high self-discharge rate -- they're not a good choice for something like a flashlight that's used only occasionally.

4. I've never found a good use for the rechargeable alkalines. Their capacity drops with each recharge and with increased current. At higher currents, the capacity decrease is even faster. NiMH or primary alkaline has been a better choice every time I've done a careful comparison.

5. The 1.5 volt primary lithium cells have more capacity than either alkaline or NiMH, especially better than alkaline at high currents. They're very light weight, have a long shelf life, and are excellent at

low temperatures. But they cost like the dickens. I keep a couple of them in my emergency kit when backpacking or cross-country skiing as a backup for GPS or flashlight, but don't use them regularly.

I've tested a good number of various alkaline AA cells at constant current loads of around 200 mA, and found only minor and inconsistent capacity differences among brands and types. Consequently, I usually use the ones I buy at Costco for about 25 cents each.

If you have a particular application in mind, check the data sheet for the performance under the conditions you anticipate. Then you pays your money and makes your choice.

Well actually, the project I had in mind was to take the 60 khz WWVB signal and use diode harmonic multipliers to create a clock in the gigahertz range. I would then use this clock as the input to a DDS system. I could use the GPS to calculate lightspeed delay between the VFO and the WWVB to determine compensating phase lag.

This could be good for synchronizing the transmit and receive ends of a digital communication, improving the signal to noise ratio.

It would be very useful. Keep in mind that all oscillators in the system would need to be coherent so a heterodyne conversion transceiver design would need to have any other LO's synched as well.

An idea that I have had is the prize for transatlantic 2 meter DX. If multiple stations stateside had same coherent carrier and were keyed (or modulated) coherently, there would be space diversity in the transmitted signal.

Have a look at AAA's for a chuckle. If we compare them by mass, one
gets 4 times less in AAA's (2 cells) than in AA's (4 cells) for the
same price. The battery makers must be giggling all the way to the
bank over this one. Howver, my remote control doesn't care if it is a
fine vintage Union Carbide or a China special. That will have an
effect eventually, especially in lost jobs.

There is another factor I've discovered for a cell's usage in audio
applications such as a battery powered portable mixer or especially an
electret microphone. Alkaline cells seem to be plagued with pops and
ticks while carbon cells are dead quiet in comparison. Since most
electret mics have very simple electronics with no voltage regulation,
the battery must be extremely quiet. Unfortunately I don't have the
numbers on hand to document my experience but this is just to comment
that sometimes there are other factors (noise) which may make a cell
type more desirable for very specific applications. For example
electric guitar players are sticklers for the type of square 9 volt
batteries that go into their vintage pedals.

I think you'll have to find a way to synchronize the startup ('reset')of all the DDS's. If you don't, they'll all start clocking at different times. The output doesn't come for some number of clock cycles later, depending on what's loaded into the counters. Because of this, you'll have "phase lock" but not "phase coincidence". Synchronizing DDS's is described by Analog Devices in an appp-note on generating quadrature signals using 2 DDS chips.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B

licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

Wow... multiplying a very noisy 60kHz WWVB signal up to the gigahertz
using diode multipliers. Astonishing. Unless you live in the shadow
of Boulder CO, WWVB will be so noisy that after multiplication
you just have a huge broad hash of frequencies. It's buried in the
hash of noise most of the time anyway. And here on the East
Coast, WWVB reception is only barely usable for a few hours in the very
early AM (and not even that if there's a broadband LF noise source
anywhere in the vicinity.)

Receiving WWV (2.5, 5, 10, 15, and 20MHz) or WWVH is not quite so
problematic (usually in the continental US one of those frequencies
is receivable) but still not easy. And in say Asia or Europe or
South America most of those frequencies will not be open most of the
time, and there are local time/freq stations on those same frequencies
often. But multiplying what is usually a noisy carrier up to the
GHz via diode multipliers is still completely unthinkable.

What *is* done is to lock a high-stability OCXO to a time/freq
standard. This is often used for extremely-narrow-bandwidth moonbounce
communications for example. In the past decade almost all of this
is done by locking to GPS satellites, but if WWV or WWVB is receivable
at both ends this has been done too.

You do have the right spirit (low-bandwidth-for-low-noise requires
an accurate frequency standard) but multiplying WWVB into the GHz
using diode multipliers is decidedly *not* the way to do it. OCXO's
are cheap and GPS receivers are cheap and GPS is receivable everywhere
around the world and PLL's are so easy to do, so that's what
we use now. Before that PLLing a crystal oscillator to WWV/WWVB (
even if the PLL was a guy's ear listening for zero-beat and a
screwdriver
to tweak the oscillator fine-tuning) was
reasonable but there you're up against propogation and varying
path-length much of the time.

They don't -- there are plenty of places in the U.S. where it takes a fair amount of experimentation to get them to sync at all. Most of them 'listen' in the wee hours of the morning when propagation tends to be better too. And finally, even if they do only manage to sync up 'once in a while' (say every week or two), they still perform much better than a typical wall clock.

>propagation and who are also interested in the
>way that their radios function. It has a long-standing
>tradition of providing a source of engineers who
>are born naturals.

It also includes an interest in communication, that being the primary
purpose for -using- a radio.

>Ham Radio

Amateur radio.....

> awakens in its aficionados a whole-life
>fascination with all things technical and gives
>an all-abiding curiosity to improve one's scientific
>knowledge. It's a great swimming pool, please dive in!
>
>This excitement causes a wish to share the experience
>with ones fellow man, and shows itself in the
>gentlemanly traditions of Ham Radio.

.....Amateur Radio.

>Radio Hams

Radio Amateurs.....

> are in a unique privileged position in that
>they can construct and operate their own equipment! No-one
>else has this privilege. Users, such as broadcasters,
>the po lice and armed farces, CBers and mobile phone
>users have to purchase ready-made gear.

Wrong. As a BE I have designed, constructed and operated two broadcast
transmitters. Anyone can build and operate equipment for any purpose

provided the equipment meets government criteria and has been
certificated (or otherwise authorized), and the operator has the
proper license or authorization.

And under those rules, Part 15 (as well as the UK equivalent) gives
hobbyists the opportunity to build and operate their own equipment
-without- a license at much lower power. That's not necessarily a bad
thing; those who have challenged the limitations of the 1750m band
have made significant technical advancements that have spilled over
into the field of Amateur radio. Part 15 also allows broadcasting with
very low power; broadcasting is prohibited for Amateurs except in very
special circumstances.

> Manufacturers
>are not licensed to operate their gear.

Wrong. They -MUST- hold a license or proper authorization to operate
their equipment for the simple reason that it must be tested.

> Radio Hams

Radio Amateurs.....

>are qualified to design, build and then
>operate their own pieces of equipment.

Wrong. An Amateur license does not QUALIFY them to design or build
anything. ANYONE can design and build their own equipment. Amateurs
are AUTHORIZED to OPERATE their own equipment, and then ONLY if the
equipment meets certain technical standards as set forth under the
rules regulating Amateur radio.

> They do this
>with gusto, and also repair and modify their own
>equipment. This is a privilege well worth the effort
>to gain, and one to be jealously guarded.

Yet it is a privilege that is not exclusive to Amateur radio.

>The excitement that drives a Radio Ham

..... a Radio Amateur.....

> starts with

>they have not satisfied any technical qualification
>and their licences prevent the use of
>self-designed-and-built equipment.

Notwithstanding the negative connotations, you described CB radio very
well. The Citizen's Band is -intended- for people who want to buy
their radios off the shelf -- not caring about how they work or any
other technical aspects beyond basic functionality. It's a plug-n-play
radio service. And no license is required (in the US).

>These CB types engage in the competitive activities
>with their Cheque-Book-purchased off-the-shelf radios
>in a forlorn effort to prove that they are Radio Hams.

Source record: 16415

Amateur Radio Frequently Asked Questions:

1) What is Amateur Radio?

In its most general sense the term Amateur Radio covers a very wide range of activities initiated by a group of people for the public good both short term and long term on a purely non-profit and non-commercial basis, using frequencies provided by a nation upon which that group performs its activities. Such a group is known as a nation's Amateur Radio Service.

2) Why Amateur Radio?

A great many national governments recognize the necessity for forming a body of volunteers existing entirely outside the commerical telecommunications infrastructure who are permitted to use radio frequencies. The necessity comes out of at least the following motivations: (a) the ability to form auxillary communications for public safety and welfare less subject to regional outage in the face of disaster, unrest, or other emergencies affecting normal communications (b) encouraging spread of scientific and technological literacy throughout the population via self training, (c) encouraging innovation in the state of the art of communications technology or in the basic sciences on which that technology is based, (d) encouraging goodwill between countries through informal communications between citizens of those respective countries with no payments needing to be made to a common carrier.

3) Who is eligible to operate an Amateur Radio?

Typically any citizen of a country whose laws create an Amateur Radio Service, who can pass a skills test in any or all of theory, regulations, or telegraphy which may be required for the safe operation of an amateur station on the frequencies granted for such operation. The skills test is usually basic for minimum priviledges and intensive for maximum priviledges. The skills test is usually administered either by a government official or by a panel of volunteers appointed by that official. Upon passing the skills test a license to operate is granted to that citizen.

4) Can children operate an Amateur Radio?

In the United States and many other countries there is no minimum age requirement for a minor citizen to be licensed to operate an amateur radio.

5) Who is ineligible to operate an Amateur Radio?

Typically anyone ever convicted of a felony of any kind, although this bar can be waived on a case by case basis through a legal hearing. Also, typically anyone whose license grant to operate had been revoked through a substantial violation of that nation's amateur radio regulations, and again, this bar can be waived on a case by case basis through a legal hearing.

6) What equipment can be legally used for operation?

In most countries any licensed amateur radio operator can build equipment either directly from electronic components or may adapt existing telecommunications equipment to transceive on frequencies designated for amateur radio. In other, more authoritarian countries, equipment may be held in keeping by a nation's government in designated club buildings. In countries governed under a civil law framework rather than a common law framework, a one-time or periodic tax may need to be paid to the government for each transmitter or receiver to be authorized for use by that citizen.

7) How much power can be legally used for operation?

Each nation can choose maximum legal power either on the basis of license priviledge, propogation or interference characteristics of the band in question, or safety considerations such as bodily RF exposure. Power limits could range from 5 watts to 2000 watts.

8) What communications can be conducted over amateur radio?

Typically only communications relating to public safety, statements of a personal nature, or technical conversations. Further, personal conversations may not involve material considered obscene or indecent as based on the standards of the nation of whom the citizen is a part. More authoritarian countries may place additional restrictions such as the banning of any communications containing political content or opinion. Limited one way communications are permitted, usually pertaining to telegraphy practice or to call outs for the purpose of initiating a two way conversation. Communications may generally not be intentionally obscured or encrypted, any published or commonly utilized language or protocol is considered acceptable for this purpose. One-way continuous broadcasting of news or music is typically prohibited.

9) Can unlicensed people ever operate an amateur radio?

In limited cases, yes. a) In genuine emergencies dangerous to life or limb, or potentially so, unlicensed people may use the signals MAYDAY or PAN respectively to call out for help or to warn away on any radio frequency, not just amateur radio frequencies. b) Anyone can operate an amateur radio under the direct supervision of an amateur radio operator using the priviledges of that supervisor. c) Anyone can use a frequency for micropower use so long as the frequency is not expressedly prohibited for such use. Power limits can be quite severe but they are adequate for use in demonstration, education, or research and development within the home or laboratory.

It is a myth that any person can transmit or broadcast unlicensed in international waters. Typically jurisdiction banning unlicensed operation extends either through the flag of the vessel containing the radio, or through the citizenship of the person transmitting.

10) How is amateur radio different from other competing informal radio operation?

Some countries do authorize citizen, family, or remote control radio services restricted to the use of government type-accepted equipment having fixed frequency channels, limited power, limited antenna size and/or height, and limited maximum distance.

Amateur radio is distinguished from these services by virtue of its special characteristics: a) potentially unlimited range, b) no restrictions to type-accepted equipment, c) transmission may take place anywhere within the designated band, d) international communications are allowed.

11) How is amateur radio different from experimental radio?

Some nations do offer upon application a legal grant for a limited number of people to operate telegraphy, voice, or telemetry upon bands or frequencies having interesting characteristcs. These bands or frequencies may later become adopted as part of the bands authrorized for amateur operation.

12) Is there a banned countries list?

Not at present. During the Cold War the United States and some other democratic nations did indeed publish a short list of totalitarian states and other states sponsoring terrorism with whom there was no legitimate purpose other than espionage for international communications, even as amateur radio operators. Such blockades are no longer in force. Instead, amateurs may not communicate with private citizens of other countries who have an objection to amateur radio. For all practical purposes this means the only country with whom amateur radio operators may not communicate with is North Korea, as that country is a totalitarian state that does not permit amateur radio.

[ ] In the UK, no repeat no licence of any kind is necessary to specify, design, construct, modify, repair, own, or (under some circumstances) test an Amateur transmitter.

[ ] A pass in a current examination for a UK Amateur Licence qualifies the successful candidate for the issue of a UK Licence. Holders of the appropriate levels of licence are permitted to operate transmitting equipment that is not subject to a formal approvals procedure, and to carry out technical investigations. A qualification for a Licence, or the Licence itself, is not, repeat not, a qualification to specify, design, construct, modify, repair, or own transmitting equipment.

>battery in an increasing duty cycle as battery voltage went down. When
>he transmitted, his load was about 2A, and it would come out of the
>battery.

>I'd like to do something similar, but larger....

Even simpler (and the way I do it): look up "float charging". Adjust
output of whatever regulated and reverse-protected DC power supply you
have handy to the proper "float voltage" of your battery (I use a plain
ol' car battery, not even a "deep cycle", as one of my HF radios starts
FM-ing when the battery drops to about 11 volts, so the increased capacity
of a deep cycle battery is totally wasted) and connect it and your
equipment across the battery!

When battery is low and equipment is off, battery is charged.
When battery is high and equipment is off, battery quits charging.
No special "charge controller" or other electronics beyond that
already in most DC power supplies is/are needed.

One can also use an "automatic" charger which cycles on and off as
necessary to keep the battery charged, but this will probably cost more
because most junk boxes probably aren't as well supplied with automatic
chargers as they are with regulated DC power supplies. But they are NOT
particularly expensive; Wal-Mart use to sell a 1.5-amp version to mount
under the hood of a car for about $25-30.

The radio (and two emergency lights) in my shack have been powered by
either of the above two ways for over 25 years.

The only two times I've had to use some kind of "charge controller"
were when the sourse was a:
* wind generator - when the wind blew, it created whatever voltage
was necessary to force about 15 amps into whatever was connected!
(I used a zener and a few transistors -- two of them big! -- to
"dump" excess current into two 100-watt 1-ohm resistors.
* solar panel - except that my panel only produced about 2 amps in
bright sunlight, the sun shown much more often than the wind blew,
so this was basically the same problem: dump excess current.

Incidentally, for not-too-big DC power supplies, I've not found it
particularly necessary for them to be very "pure" DC; a 60-amp-hour
car battery acts like a pretty-big filter capacitor!

I bought a Weller gun recently to unsolder some can capacitors from a steel chassis. I was totally dissapointed when I got home and unpacked the gun. This gun is not the same as my daddy had about 40 years ago. It was a cheap piece of shit. I tried with all my might to get that thing to work. The tip was flimsy, the set screws to connect the tip were flimsy and the two tubes that come out were so flimsy that they would short themselves out whenever a little bit of pressure was put on the tip. I tried boosting the voltage into the gun until the core was humming real good. With about 140v into the thing the plastic handle was too hot to touch and I could see smoke coming out of the handle. I took it back and told the guy at the True-value store it didn't work and smelt funny when I used it. I told him I thought the secondary was shorted. Heheh.

Nope. I got it, but I see your point. The issue I was thinking of was the fact that the hot air "pre-heat" will still take longer than a high heat-capacity tip, thus allowing more opportunity (time) for the dielectric to soften and deform if it isn't held well, without stress applied. I think RG-8 size is probably less of a problem. RG-58 tends to easily allow the center conductor to travel if given the opportunity.

My hot plate also only "warms" the ceramic so, when touched with the iron for the heat-to-solder phase, it doesn't do that almost imperceptible TINK! from the almost invisible crack across the ceramic due to an all to large temp gradient.

How long do you take in the warming phase before doing the actual heat-to-solder phase?

I have a professional resistance (dental brace) soldering machine (by K9PGN - SK) and it is considered tops on methods...by some, of course.

Yep, a bunch of NPO in parallel is a good way to go. Polystyrene is
nice too. BTW you can get some very impressive amounts of capacitance
out of multilayer ceramic capacitors.

Suggest you buy a butane (cigarette lighter gas) soldering iron with
adjustable gas flow to change temperature.
These irons come with different kathalytic burner bits and have a capacity
of well over 100 Watts equivalent.
Electric soldering guns are prone to failure and don't sink much heat into
the object to be soldered.

Hm, everybody has his own solution. I happily use an old Weller gun or small butane torch for putting a PL-259 onto an RG-8 size cable, as I have for decades. I keep the cable straight so the center conductor ends up where it belongs when the insulation cools. I never use PL-259s for RG-58 or RG-59 size cable anymore -- I always use BNC instead. I've got a box full of adapters to use whenever I need to connect to anything else. Both BNC connectors and BNC-to-anything adapters are readily available on eBay. Actually, I don't use RG-8 size cable very often, and recently I've been putting N connectors on it when I do.

I use my old Wen model 450 gun with a 45A7 heavy duty soldering tip. This combination is powerful enough to solder the old fashioned galvanized roof spouting if necessary.

If you want some *real* heat, rip the carbon rods out of a couple of C
or D batteries. Cut just one wire of a bedside table lamp in the middle.
Strip the ends and wrap one wire around one carbon rod and the same
with the other on the remaining rod. Hold the rod ends clamped by
wooden clothes pins so that the wires are pressed into the rod. Keep
the rods apart and plug in the lamp. Turn on the lamp, then bring the
rods close together. You should develop a nice arc that will blind you
momentarily and leave you seeing blue spots for a few hours. However,
the arc will have been hotter than the surface of the Sun. But you can
melt paper clips and glass marbles with it. A welders mask may help
with the spotty vision.

Disclaimer: Do not try this in the shower. Objects may appear blurrier
than they really are temporarily but perhaps permanently. Results may
vary with the wattage of the bedside table lamp.

I think you'd have a difficult problem with the variable phase due to
multipath causing shifting path length between both ends of the digital
communication.

That is why systems may use time based coherancy for data start and stop
times, and so on, but do not bother to try for radio carrier frequency phase
coherant systems.

How cheap is cheap?

What is nothing fancy?

Is the use of a PC a requirement?

I'm in the process of building a controller myself. Check this link for
current status:

http://home.swipnet.se/sm4rpq/elec/slcrc/slcrc.html

I'd say you get away with something around 5-15$ depending on you
junkboxes size.

Warning, there are some dead links on it and no diagrams yet.

It's not necessary to provide a "dump" for a charge controller when a solar panel is used for charging (at least the ones we use at work don't require a dump). It appears the charge controller shorts the "array" connections and the panels circulate their "short circuit current" around the array loop.

Hi,

I am working on building a VCO for FSK with 850 Hz separation between mark and space. I am building it using a 16.000 MHz 32pf parallel load crystal. I am pulling the crystal via a varactor to implement the FSK. However, the amplitude between mark and space is an unacceptable 10 dB with about 700 Hz of shift. Any ideas on how to pull the crystal without changing the amplitude of the mark and space frequencies considerably?

A bit about my circuit: have an 8 - 50 pF tuning cap across pins 6 and 7; a 22pF cap shunts pin 7. The crystal shunts pin 6. A 100nF DC block cap separates pin 6 from the 8 - 29 pF (3 to 10 V reverse bias) varactor. A 1mH inductor isolates AC from the varactor biasing.

I tried adding 1uH of inductance in series with the crystal. This moved the oscillation frequency up, but the amplitude problem remained. I tried putting the varactor across the tuning cap. This configuration exhibited the same amplitude shift problem, but shifted the frequency up rather than down. I tried combining the two shifts via two varactors and a JFET to invert the biases, one across the crystal (as originally) and one across the tuning cap. This didn't work well (very noisy spectrum).

Any ideas as to what could be the problem and how to fix it?

Cheers,
Chris

The comment below is valid if there are only solar panels involved.
However ,when these are used in combination with a wind generator a current dump is required.
My battery operated station has its batteries charged by this combination of sources.
The home brew charger comprises a zener referenced comparator (741 opamp) driving a number of power transistors ,with the rest of the load being a number of car head light bulbs.
When the batteries are fully charged ,all current generated is dumped .its resulting heat making a minor contribution to shack heating.

==========
Perhaps is it useful to mention that PL259 type of connectors for 3/8inch
(10mm) OD coax are available with a cable entry as per a standard
N-connector eg a metal braid sleeve with rubber cable compression ring.
The only soldering required is for the centre pin.
The ones I use are of a high quality ,having a gold-plated centre pin . They
are made in Taiwan ; the UK price some time ago was GBP 3.00 (US$ 5.50) .
Perhaps a bit expensive but well worth buying.

Frank GM&#65533;CSZ / KN6WH

Chris, when you capacitively "pull" an Xtal, you lower the Q of the tuned circuit hence the amplitude of oscillation varies with the capacitive loading on the Xtal.

This is not so much a problem as a natural effect that requires compensation.

Arguably the easiest way to compensate for this is to simply drive a switching transistor or IC into saturation throughout the range of amplitude variations that the oscillator experiences. Essentially, you're buffering using a quasi Schmidt Trigger arrangement, which produces a constant amplitude output.

I believe that the problem that you'll eventually face is how to keep your 850-Hz shift constant and centered. When I was active in FSK TTY, my solution was to incorporate a monitor scope with filters into my VCO, plus provide real-time adjustable shift and centering adjustments.

Hope this helps.

Chris, here's a question for you. (I'm assuming that you are working with FSK TTY.)

Is the classic 850-Hz shift still the current standard as it was during the 1960s when I was still involved in TTY? I had thought that it had been reduced to something like 75-Hz during the 70s due to the problems with propagation path differences over a 850-Hz frequency spread.

Also, back in the mid-60s, it was sort of presumed that AFSK would soon replace FSK... Did that ever actually happen?

By the way, in those days we tested our terminal units by printing NSS transmissions for hour after hour. You could then visually scan down the pages of printed code groups to determine how often your system produced a glitch.

I was then among the more fortunate, because I owned a Model 26 TTY, a model 14 Transmitter/Distributor, plus the holy of all holys, a Model 14 typing reperforator. Today all of these have been replaced by computers! :-) Still, hearing those old machines hammer and click away provided much more gratification than does a computer!

Have fun, Harry C.

I'd look at your circuit. Thats a very large change for a small shift
at 16mhz. Nominally I'd expect only a tiny change at 16mhz and no
where near 10db. From what you say it sould like your using
a NE/SE602 or similar as the osc and it may be the constants
you are using are off. it also may be that the varactor you using
is getting foward biased and that will alter the oscillartor output.

For a simple shift a series cap and a diode switch is adaquate for
a shift like that. To dial it in the cap can be variable. There are
plenty of published circuits that already do this in various CW
tranceiver designs for RX to TX shift (sidetone too).

An alternate is live with it and add a limiting stage after it
(74HC04s) to take out the amplitude change.

Allison

I don't know when the 170 hz shift took over for most use. It was being used about 25 years ago on the low bands for most of the users when I first started rtty.

FSK is still all that is allowed on the low bands. Today it is generated by using a SSB transmitter in the SLB mode and feeding in audio tones. This generates a signal that is the same comming out of the transmitter as a FSK transmitter. That is possiable due to the way a ssb transmitter works. If the same rig was switched to AM or FM them it would be AFSK.

YOu can go here and download some programs that you can use on the computer to do the digital modes. As I mentioned above by feeding the audio tones into the mic or audio input of a ssb transmitter you will be generating FSK eventhough it might not seem so.

http://www.muenster.de/~welp/sb.htm

One of the best free programs to get started with in rtty is the MMTTY program.

It doesn't seem to be a problem with either size of cable, largely
because the dielectric doesn't get hot enough to melt and become runny,
and also because the center conductor isn't trying to move off-center
anyway.

>My hot plate also only "warms" the ceramic so, when touched with the iron

Ah, now I see what you're using it for.

>How long do you take in the warming phase before doing the actual
>heat-to-solder phase?
>
About 10-20 seconds with a 2kW hot-air gun.... but that obviously
depends on a lot of other variables, particularly the power of the
electric iron to follow.

My worry with many of the "big iron" methods is that it's very hard to
be sure you have a good solder joint, all the way down the sides of the
hole. More often, I suspect it makes a good joint to the braid but a
cold joint to the sides of the hole. This may look OK, but the plug of
solder may eventually work loose in the hole.

A handy trick is to enlarge the holes with a drill or reamer or to make them slightly oblong with a small triangular file. I've seen some connectors with an oblong opening as standard. It does make for easier soldering.

I just need something for $50 or less to give me a hang timer and time-out timer. A CW ID would be a bonus. No a PC is not required. You controller seems it may do the job. Is it complete yet?

Thanks for the links. I didn't know you could get a NHRC-2 kit for that
price. I think I may try svxlink as well.

Source record: 16445

Thank you all for your informative replies.

Turns out I had two problems. One was that my scope probe capacitance (30pF) was loading the oscillation. However, the spectrum analyzer is sensitive enough though that if I simply place the probe close to the oscillator, the radiated signal from the oscillator is picked up.

The second problem was my bench, for I tried the antenna probe trick before without success. I had the solder joints on my board touching the ESD protection mat that was acting like a semi-conductive surface I think. Once I placed the board on spacers the issue resolved itself.

I now get about 2kHz of tuning over 9V with 2.8dB of amplitude change (this includes a slightly non-linear region of the varactor in the last 2-3 volts). Selecting an 850 Hz interval and applying a 100 Hz modulating square wave produces a beautifully symmetric FSK spectrum.

Cheers,
Chris

Hi Frank,

OK, I see. I made an assumption on my part that you meant only one or
the other (solar or wind) was being used. So, what you are saying is
that one charge controller is being used with two sources attached to
it? If so, I would agree...

From a manufacturer's point of view AA and AAA probably cost about the same. Small long tubes are harder to draw and fill without rejects. What really annoys me is the way designers are pushing toward AAA in LED flashlights and small portable radios to keep the weight/size down. I would much rather have AA.

That is essentially true also for the US. The amateur license is
ONLY needed for "on-the-air" operation of a transmitter.
In contrast, anyone can construct and operate a reciever.

I think that can be generally said as true also for the US.

Yes, it's a reasonably common theme that seems to have been totally
missed by this chap. It makes one wonder if he has a full grasp of his
Licence conditions

>> [ ] A pass in a current examination for a UK Amateur Licence qualifies

The other thing to be aware of is that this chap, in this sock-puppet
and his innumerable previous ones, has alternately decried e.g contest
operating as being the act of a "CBer", and then swung completely
about and used it as a justification for the description of a 'radio
ham'. I've lost count now of how many times this circle has been gone
round. It must make anyone who is keen on becoming a 'radio ham' very
confused, as the fundamental basis on which it is built changes so
often!

I wonder where the law stands as far as CB radio's go. Are CB's allowed to be repaired by the average CB'er who has the knowledge or are they only repairable by a qualified technician of some kind. I ask along the lines of the UK but would find the answer for America just as interesting.

Regards,
Graham

I can't answer your question, but perhaps this is one of those cases
where it is better not to ask, but to carry on as before. Having a
piece of gear repaired by a certified authority will probably cost
more than buying a new one....

Thanks for that, quick answer too :o)
I would agree about the cost from a Certified Authority as most CB's in the
UK are only worth between $26 - $52 and the repair bill from a qualified
"tech" would be more than this... and would they indeed bother as they could
make far more money with the same effort repairing other items more
valuable...
I was just curious as to the legallity of repairing a CB. I wasnt admitting
to anything.. honest .... ;o)

LOL!

Unfortunately, Amateur Radio has seen increasing restrictions placed
on it due to people seeking 'clarification' from the authorities,
rather than enjoying freedom given by the sometimes loosely-worded
regulations....

I'm not sure why this thread is even being cross-posted into a CB group, but
to answer your question, in the US, the radio must be serviced by a
qualified, licensed individual. That is the "legal" way of doing it anyway.
It doesn't happen very often, but that is another story for another time...

Get a new rule book like one that is newer than say about 10 or so years.
The CB radios in the US has not required a license to repair them in many
years. The GROL is the replacement for the 1st and 2 nd class licenses that
used to be required to repair many transmitters. For about 95 % of the
transmitters in the US it is now worthless and not needed. Some companies
may require it as they think they are getting someone that may know
something. Now it is only needed for :

****
General Radiotelephone Operator License (GROL) is required to adjust
maintain, or internally repair FCC licensed radiotelephone transmitters in
the aviation, maritime and international fixed public radio services. It
conveys all of the operating authority of the MROP.

It is required to operate the following:

any maritime land radio station or compulsorily equipped ship radiotelephone
station operating with more than 1500 watts of peak envelope power;

voluntarily equipped ship and aeronautical (including aircraft) stations
with more than 1000 watts of peak envelope power

****

Go here for more info on the licenses that are now issued.

Thanks for that. So the theory i get so far is anyone can build an Amateur
radio but they cant "repair" a CB radio.... lol.. it is a crazy world

See comments above about license not needed any more for CB repair in the US.

It used to be the Amateur tests were about on par with the comercial class licenses. The main differance was just the regulatory rules and not the electrical part. That was about 1972 when I passed the 1 st class license. The way they are now anyone with a good memory can pass the tests. My wife passed the Technichan class about 1987 or 88 just by memorizing the Q&A pool. She doesn't know or care about the technical part of radio.

I generally stock up on Energizer batteries by buying them in the bulk pack from Home Depot.

For AA Energizer Max Alkaline cells, a package of 36 is $9.75 or $0.27 each. AAA, C, D and 9-volt batteries are similarly discounted. Home Depot seems like an odd place to purchase batteries, still they have the best prices by a wide margin.

I've personally had bad experiences with Duracell Copper Tops (very erratic cell life when used in series), so I switched to Energizer and have never seen that problem again.

let me clarify what I mean by a bad experience. My hand-held Lorain receiver uses (IIRC) 9 AA cells connected in series. Using Duracells, I've twice had one of the 9 batteries prematurely fail, with the remaining 8 only partially discharged. Consequently you replace all 9 cells. The first time this happened I was just sitting on my boat playing with the Lorain. The second time it happened was in the middle of a line squall while 4-miles or so offshore of Cape Ann in Massachusetts. When I asked the Lorain to take me home, it faltered and quit due to the premature failure of one of the Duracell batteries at a time when I was nearly knee deep in water in the boat's cockpit (it's a 23' Hutchins Compac cruising sailboat). As a result, I was damn lucky to reach the shelter of the Annisquam River while believing I was entering the inlet to Plum Island Sound at Ipswich under nearly zero visibility conditions.

It surfices to say that I will never again purchase a Duracell battery. They are not reliable. Energizer seems to be.

Just my experience, which I thought that I should share with others.

Harry C.

Roy Lewallen <w7el@eznec.com> wrote:

| Only a few rules of thumb can be put forth:
|
| 1. For heavy drain applications such as photoflash or an HT, alkalines
| last many times longer than "heavy duty" carbon-zinc types, so the
| latter is seldom an economical choice for those applications. Likewise
| for applications with moderate but constant drain such as a GPS
| receiver. Carbon-zinc is probably more economical (unless you use
| alkalines from Costco or other discount store)

... well, if you're looking for the most bang-for-your-buck, you
SHOULD be getting the non name brand alkalines :)

Personally, I've not found carbon-zinc batteries to be more
economical, unless you're not actually using them.

| But I don't use carbon-zinc for anything.

Me neither.

| 3. Modern NiMH cells have about the same capacity as alkaline cells

In my experience, the alkaline cells have higher capacities, about
twice as high.

| more at very high currents -- and the capacity is quite constant
| over a wide range of discharge conditions.

And this is very true. The alkalines suffer greatly if you discharge
at a high rate, where the NiMH cells do just fine.

| A down side is the high self-discharge rate -- they're not a good
| choice for something like a flashlight that's used only
| occasionally.

Yup. NiCd cells are better, but still nowhere near as good as
alkaline or lithium cells with regard to self discharge rates.

Even with moderately high self-discharge rates, I'm finding NiMH AAs to be a good solution for most applications where I use AAs. I just cycle them through the recharger occasionally. I have enough extras, and recharging is so fast, that it's not a problem to me if I forget and let a set discharge to where I have to put in a new set. Noteable exceptions: very low drain devices like smoke detectors and remote control transmitters that will run for a year or more on alkalines. Digital cameras, particularly, show off the advantages of the NiMHs: alkalines just don't cut it in mine (unuseable after five or ten pictures, compared with dozens for one charge on NiMHs), though I've heard that the alkalines specially designed for digital cameras are at least useable.

There's a lot of misinformation about batteries of various kinds out there. I've found http://www.batteryuniversity.com/ to be an easy to understand source of generally very good information about a lot of different types of batteries. It mostly covers rechargables, but there's some info about alkalines in there.

A friend who uses alkalines in his insulin pump told me he was surprised to find that, in that particular application, he's seeing a significant difference between standard Duracell and Energizer alkaline AAs. "Your mileage may vary."

Cheers,
Tom

Well MFJ did not tell you the whole story (typical of them BTW)

They do have the Curtis 8045ABM (28-pin chip) that can be adopted to the
product. Some older 8044 chips (14-pin) do appear from time to time.

I've always had horrible luck with Duracells. Every five years or so I go out and buy another set to remind myself of this, but the results are never different.

Harry G. mentions getting good prices on Energizers at Home Depot. Seems like the HD stores around here never ever have the good deals I read about from other people on the 'net; batteries there are about the same price as Walgreen's around here. People talk about borrowing free tools to replace cartridges in Moen faucets and then getting free replacements at HD; ours will sell us a plastic tool for $18 and then we get to decide which size cartridge is appropriate, at full retail price, of course. But the (local?) Menard's chain usually has Ray-O-Vac AA's at 30 for $9.99, and I get great life out of them, nearly as good as the Energizers for about half the price.

Roy Lewallen mentions Costco; they haven't had their particular brand (40 for $10) for literally years here, all they sell is Duracells now and they want 25% more than Menard's and the Ray-O-Vacs.

Doug McLaren mentioned his experience that alkalines have higher capacities than rechargeables, but I'm finding that my new Eveready 2500 mAH NiMH batteries compete quite well with a fresh set of Energizers. KenRockwell.com lists alkalines at 2700 to 3135 mAH, sounds reasonable.

I would guess a fair amount dont really care about the technical side or would want to build their own radio and linear. You would have to be pretty dedicated for that. I would also guess at most Amateurs are happy just talking legally with a licence and a stock bought radio and antenna. Not that theres anything wrong with that, it just depends on how serious you take the hobby. Like the M3 foundation licence. It suits a lot of people who are.. disillusioned with CB and want to go Amateur but not really wishing to get so involved with the whole technical side of things. There are some good M3 people out there whatever the old school say, but i agree they will never be on a par with a full licence holder but is that such a terrible thing.

5039. High-insulation 1:1 wideband transformer?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-07 22:00:56 UTC
From: SpamHog <n1jpr@hotmail.com>
Message-ID: <1131400856.737888.155950@g49g2000cwa.googlegroups.com>
Source record: 16322

I have a T2FD antenna for 5-20 MHz next to a good ground point,
and I'd like to make the lead-in coax DC-insulated
to lessen the risk from a lightning strike.

I would line to put in a wideband RF transformer with
1) primary connected to the antenna coax and the ground
2) secondary connected to the lead-in coax, w/o any DC connection at
all.

This is a low power / RX installation, and a bit of loss should not be
a problem. There are already a few neon lamps in the T2FD balun, and
I'll add a spark gap at the primary.

I am very tempted to use either a toroid or a couple of ferrite rods
with 1:1 windings made of... spark plug wire?! The stuff takes 30kV
pulses without even blinking, If I use non-resistive type, an
appropriate container, and keep it all dry, breakdown voltage between
incoming and outgoing coax could exceed 50kV. A low-ohm, low-Z
grounding could help ensure that it's not easily exceeded.

Hopefully, very little pulse energy would come my way.

Any thoughts?
Any pointers to plans for high-insulation RF transformers?

5040. Sentry projects in Elementary Electronics Magazine.

While cleaning out this weekend, I found a small collection of
printed circuit boards that I got from Elementary Electronics 1967-68.
They're not really worth anything, but it would be fun to know what
they are. I can't find them using Google. The dates are scratched on
the boards and the names are part of the etch.

1: Sentry Multivibrator, May 1968
2: Sentry Lo-Frequency Oscillator, March 1968
3: Sentry Hi-Lo Bander, July 1968
4: Looks like a wireless mic, no name (has 9V, ANT, SW and MIC on
the etch), Sentry, Nov 1967

These were distributed via blister pack (IRC).

Just curious.

Steve.

A good RF ferrite toroid would out perform the rods, especially at the
low frequency end.

Perhaps something like the FT-240-43 on this page:
http://www.surplussales.com/FerToro/FerToro-1.html

> with 1:1 windings made of... spark plug wire?! The stuff takes 30kV

The silicone wire made for the high voltage connections to cathode ray
tubes is smaller per voltage rating than ignition wire, I think.
It is generally more flexible, also.

Something like:
http://www.surplussales.com/Wire-Cable/HVWire-1.html

If you have a fair ground at the antenna, I doubt you need more than
5kV rated wire, since the arc would have to pierce two wires, and the
instantaneous breakdown voltage is quite a bit more than the rating of
the wire.

This is important. There are TWO things to consider. Wattage and heat capacity. Small tips have low heat capacity. A 100W old fashioned "big birtha", the kind with the 1/2 inch diameter, 2-1/2 inch long tip will out perform ANY "gun" when trying to do large work. You need that stored up heat to heat a large thing.

I don't have any problem with the ones that just want to talk. There are many good hams in public service providing communications for emergencies. I know one ham that got his license many years ago so he could fly his radio controled airplane and use 6 meters where there were few others using that frequency.

I do wish that the test could be hands on for a few simple things such as installing a coax connector and and using a simple SWR meter. Also it should be required to have a ARRL handbook or equivilent in the shack. Would not even have to be a new one, but one 10 years old would be ok. Not that many would really read it but it could answer some simple questions.

Tracking the carrier would require the clock receiver to be on all the time. All the clocks I have, including my DCF77 unit, read the time code and set the clock. If the signal is weak, they keep trying for 5 minutes or so. The most common is every 4 hours. They then free run from an on-board crystal between sets.

With the upgrade to WWVB, there is at least one period in the whole US were the code can be recovered. This is a lot easier than recovering the carrier. Clocks only display seconds, and sometimes only minutes, so gettting the code right is pretty easy. When you first set up a clock or change the battery, it might take a diurnal period to get the time set.

Over the years I have noticed misreads-- 1 minute off, or 1 hour off-- which are corrected at next read period.

Steve.

The capacity of alkaline cells is much more dependent on discharge rate than that of NiMH cells. Note the capacities of alkalines shown at the bottom of the list at http://www.imaging-resource.com/ACCS/BATTS/BATTS.HTM. With the 5 ohm load used for those tests, the alkalines have less than 800 mAh capacity. The capacities you quote would be obtainable only at much lower current drains. But I didn't look carefully at the page to see if he used a different cutoff voltage for the alkalines. A NiMH cell is just about fully discharged when its voltage reaches 1.0 volt, so that's a common cutoff voltage for testing and using NiMH cells. But an alkaline cell still has considerable energy remaining at that voltage -- a device has to function properly down to 0.9 volt, or at high drain more like 0.8 volt per cell to extract all the energy from it.

This is yet one more confounding factor in trying to compare cells of different chemistries. Performance depends heavily on the particular application and conditions of use, so a single answer to which is best, or even which has the greater capacity, simply isn't possible.

You don't need to take my word for any of this -- data sheets for common cells are readily available on the web, and it takes only a few minutes and a bit of poking on a calculator to discover this from the curves.

Harry;
9 cells is really an odd (no pun intended) number of cells. Are you sure that all were from the same date code. For example an 8 pack is a common purchase, so if you take 8 from one pack and the 9th from another, you might have an older cell in the bunch. Secondly, I have seen several products that mechanically chafe the battery wrapper. If this happens a cell will short out and overheat.

My family and I were in NYC the week of the big blackout , we left just before it happened!. As it happens. I bought some copper top batteries from a street vendor 12 for a buck. I got to the hotel and my son noticed they were chinese imitations called "powercells". They weighed in at about a third of a duracell and lasted about 20%!! I bet there were some unhappy campers in Manhattan when those batteries gave out!

After checking out the patent no. 1626391, I misread the number previously.
It was patent in 1927 so I guess it was for TRF receivers, giving them a
wider tuning range and perhaps a neater dial cal. Does anyone recall who
might have used them?
tnx

My Handbook (not ARRL) is much older, but I wasn't aware of any change
in the physics in the interim. Why choose ten years? The Admiralty
handbook is still relevant - and can answer questions - even if the
units have changed. You appear to be a newcomer.

Thank you John! I hadn't thought about CRT wire!
It surely is more flexible, which is necessary for threading
several turns through a toroid.

I happen to have the right toroid on hand, I'll get the wire.

Hmmm... I could also look at the curbs for discarded TV sets,
but I don't like the risk of getting zapped by residual charges.

The real question is the grounding impedance.

You might even be able to measure the grounding resistance at DC or 50/60 Hz, but measuring the grounding impedance at a few hundred kHz might be a bit problematic. Assuming the direct lightning hit is about 10-30 kA, a grounding impedance of only 1 ohm would create a potential difference of 10-30 kV.

I do not know your mains wiring practises, but assuming that a separate mains grounding electrode is used for each house, the grounding impedance should be measured between the antenna ground and house ground. If not, the grounding impedance should be measured against some distant point.

Assuming that the house has a separate grounding electrode and your antenna will get a hit, which is conducted to ground. Due to the finite ground resistance, the house grounding electrode will move to an elevated potential (several kV) compared to the surrounding (mains neutral, telephone and CATV).

Thus, I think that the 50 kV isolation between your antenna and receiver is more than enough and I would guess that more damage would be caused due to the mains neutral, telephone and CATV connections to your equipment.

OK, if you want to get technical, a "license" per-say is not needed, though they still need to be "certified as technically qualified to perform transmitter maintenance and repair duties in the private land mobile services and fixed services by an organization or committee representative of users in those services." - Reference FCC Part 95, Section 95.424 subsection "b".

And as the question that was asked, in relation to the US:
"Are CB's allowed to be repaired by the average CB'er who has the knowledge or are they only repairable by a qualified technician of some kind[?]"
The answer to the first part of the question is still NO, and the second part is still, YES. The "average CB'er who has the knowledge" can NOT service their own CB, legally. They would need to be "certified" to do so "by an organization or committee representative of users in [the CB service]."

Not
> that many would really read it but it could answer some simple questions.

I quite agree. I also personally think to obtain a CB licence (UK im talking
here) there should be a small test.. nothing complicated, just wiring on a
PL259 correctly and how to use a SWR meter (as you say for Amateur too).
Thats two basic things ive seen either ignored or very badly done.. ie.
someone twisting the inner and outer of the co-ax together and shoving it
through the hole in the PL.... then they wonder why the radio they just
bought off you wont get out.... or someone say..swred an antenna?? whats

that then?? sheesh..
Exceedingly unlikely now as to all intents and purposes the CB band isnt of interest to the authorities that be.
Oh well..............

The 10 year number for the book was just one out of the air. Older would
have been just fine. My first ARRL hand book was bought in 1966. I did
not get a ham license untuil about 1972. Had a 1 st class radiotelephone
license around the same time. I have only used RTTY with an old mechanical
unit, been keeping up a repeater for close to 30 years, I did write a rtty
program for an old 8080 processor when I got tired of hearing the noise,
used a few of the newer digital modes with the computer, worked a few of the
OSCARs, active on 144 and 432 ssb. I do work some of the low bands also.
Guess that still makes me a newcomer to many.

There was an article in Antique Radio Classified some years ago that
made me aware of capacitors with tapered plates.

You can look up that patent online www.uspto.gov, click on search
under patents, click on patent number search, put in the number,
and when it tells you click on images. You have to have a tiff viewer
plugin in your web browser to read them. That particular patent seems
to apply to a capacitor with flat plates, so perhaps there was a pending
patent on the tapered plates.

A variable capacitor with semicircular plates and the axis of rotation
going through the middle and flat plates gives of course a linear
relationship between capacitance and angular rotation. By altering the
plate shape a bit and moving the axis of rotation off-center you can
get a capacitor that tunes straight-line wavelength. Wavelength is
proportional to the square root of capacitance. In the early days of
radio wavelength was often specified instead of frequency.

You can make a variable capacitor that is straight-line frequency, which
rotation has to be proportional to the reciprocal of the square root of
capacitance. With flat plates this requires a fairly radical plate
shape, with the axis of rotation very far off center. As a result there
has to be a lot of empty space for those long narrow plates to swing around.
I'll post a picture of one of these to that binaries group.

So a way to get around the odd plate shape and the space it occupies
is to use plates of tapered thickness. It would be nice if you got
straight-line something, but even if you don't you have something
where the stations are more spread out than they are with straight
line capacitance.

I have an old TRF receiver of the vintage of multiple knobs and 01A tubes
that uses capacitors like this.

The problem with that is it essentially means that every now and then,
in order to keep within the licence terms, one has to purchase a book.

Here in the UK we have problems with an organisation that has put
itself in the position of 'representing all UK amateurs', and which
sells books. It clearly does not do the former, and merely to add to
its coffers as part of the licencing conditions is a battle which it
has recently fought and looks like losing heavily.

>Older would have been just fine.
>My first ARRL hand book was bought in 1966.

Then why specify a time limit? Or even to have such a book in the
first place?

There is nothing wrong with your Amateur CV. The issue - at least for
us in the UK - is the grasping self-interest of the 'national
society', which has been so clearly revealed by recent events, and to
which your proposal would add succour; that was really the point of my
post.

Paul,

You make some interesting points.

>> The real question is the grounding impedance.
>> measuring the grounding impedance at a few hundred kHz
>> might be a bit problematic.

Most sources claim the energy is concentrated between DC and a few tens of kHz. This means that impedance is an issue, but not a terrible one. Typical faraday cages (few make lightning "rods" anymore...) are anything but low impedance, yet thick enough to take 100kA without melting.

>> Assuming the direct lightning hit is about 10-30 kA,
>> a grounding impedance of only 1 ohm would create
>> a potential difference of 10-30 kV.

Right. Perhaps even worse on the high end of the spectrum.

>> the grounding impedance should be measured
>> between the antenna ground and house ground.

This reminds me of a web page from your corner of Europe:
http://www.kolumbus.fi/oh5iy/back/Ham%20Radio.html

The take-home point is that one wants all sensitive equipment (and people) to be on a high-insulation, high-impedance branch of a multipath graph, while bolt energy is offered a low-insulation, low-impedance branch to run through.

There are interesting implications:
>> Assuming that the house has a separate grounding electrode [...]
>> due to the finite ground resistance, the house grounding electrode
>> will move to an elevated potential (several kV) compared to the surrounding
>> mains neutral, telephone and CATV).

Not necessarily. If grounds are separate, inter-groundpoint resistance will if anything decrease the risk of such an transient. If there was a single grounding point, and ground resistance were high, there would be a greater risk of the grounding point becoming a source of common mode transient towards the land lines.

In my case, my shack is at the ground floor of a 9-story building, the antenna is on top, and all grounds are pretty heavy duty and bonded - but not low impedance. The risk for the land lines would be about the same w/ or w/o my puny 20m-long T2FD. (The Other Guy has a 35ft self supporting lattice with tribander, 4x15 @ 144, 3x32 @ 430, 2m dish @

1296, weather turnstyle, 40/80 dipoles, collinear @ 144, and a 6m moonbounce dish @ 430. When I added the T2FD nobody noticed).

As for the DC block, I think I found the right container and location. A 1 - meter PVC pipe that will hang horizontally under a roof edge less than 2m from the flue lines. Pipe and coax can tiptoe away from the chimney in a environment that stays dry when it rains.

I forgot to mention... the grounding is via two massive, parallel
steel flue lines, each a foot in diameter, that drop straight to a big
pig-iron furnace underground, all bonded to the common building ground.

I had assumed that you lived on the ground level and had the antenna
feed point somewhere further in the garden.

In your actual case, assuming that the separate grounding wires come
directly down from the roof and connected to the grounding of your
apartment at the ground level and assuming that the lightning bolt
rise time would be 1 kA/us. A thick wire has an inductance about 1
uH/m, thus, there would be a voltage gradient about 1 kV/m along the
grounding wire. If the antenna system grounding wire from the roof is
30 m long, the isolation transformer primary side potential would be
30 kV above the building neutral bar and also 30 kV above your
apartment potential as well as 30 kV above the isolation transformer
secondary. The building ground bar potential will be somewhere above
the average potential of the surrounding countryside.

With 50 kV isolation at the transformer, nearly 2 kA/us rise times
could be tolerated. To reduce the grounding wire inductance, several
grounding wires would be required well separated from each other.

That should reduce the inductance considerably and thus the antenna
structure would be much closer to the building grounding bar potential
during a lightning hit.

I need to buy or build a bench power supply to test & design various tube equipment (audio & ham). I would like it to be something like a Heathkit HP-23 with voltage & current meters. The major problem with the supplies I've come across such as the HP-23, is that the B+ current is appx. 100ma. The bias & filament supplies are OK, but at times I need around 400ma for the B+ out. Is there such a PS available, perhaps with tube regulation & rectification or do I need to build from scratch? Any answers will be most appreciated.

Hallicrafter, Telefunken, Nordmende, etc all used similar caps in their TRF recievers, as did ARC5,ARC 7, and quite a few of the communication transcievers used in the late 30's early 40's. I had operational ARC 5 and ARC 7 with the external Antenna Tuning box in the late 50's. Made nice QRP devices excepting the QRM generated.

==========
An excellent design for a HV power supply unit can be found in QEX July
/August 1999 pages 50 -55
"A regulated 2400V power supply" ,by Al Williams VE6AWX

Even if you don't need such a high DC voltage ,the design is universal and
the output voltage is adjustable.
The design includes 2 SCRs in the transformer's primary winding circuit ,
with DC feedback resulting in a very stable DC supply voltage under large
load variations . Another feature is the 'soft' start preventing large
surge currents.
The author uses the unit to supply 2x813 tubes in a RF amp. requiring up to
1kW of power , with the no-load voltage of 2400V-DC dropping to 2397V when
load is 1kW.

If you don't want to DIY it, consider using a Sorensen -- some of their HV switching supplies are incredibly inexpensive on EBay. You can also look for the older Lambda and Kepco supplies with 6550 or 6L6 pass elements -- the one pictured on the link below will do 300 ma -- voltage is controlled by a variac -- you have to look both at the Business+Industrial section of the Bay as well as "Vintage Electronics".

http://www.tech-diy.com/images/lambda2.jpg

I use this microprocessor controlled power supply modification for the Heath IP-17 -- but I figured out the compensation network so it is now beautifully regulated:
http://www.tech-diy.com/MCTracer_no_pix_files/HV_MCU_webversion.htm

you can (and should) increase the current capacity for the big IRFPG40's by paralleling several units (with appropriate modifications) so that they operate in the SOA. One is not enough for your application.

5075. Controller for handheld scanner

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-10 16:21:25 UTC
From: Ceriel Nosforit <firstname@saunalahti.fi>
Message-ID: <pan.2005.11.10.16.21.24.906032@saunalahti.fi>
Source record: 16358
Cross-posted to: rec.radio.amateur.homebrew,alt.electronics

Heya,

I'm going to build a controller for an IC-R5 handheld radio scanner for a computer science (digitech) project. The idea is to be able to type in the frequency I want in my computer and then have an electric motor dial in that frequency on my scanner. I'll be using a stepping motor and some controller the circuit design of which seems to be a homebrew of the polytechnic school I attend. What I'll be doing is programming the logic of the controller and writing a computer application for Linux which tells the controller what to do.

My question is; do you know of any projects similar to this? I'm mostly looking for inspiration and pitfalls to avoid. Any comments and insight you might have is most welcome.

Now the following part probably isn't relevant here, but I just wanted to tell what I intended to do with it.

On the computer-side of this I intend to have some more advanced functions. My program will be able to accept a list or range of frequencies and then tell the controller to dial them in order.
The headphone output of the scanner is sent to the microphone jack on the computer. My program 'listens' for any sound and if it find a signal it stops telling the controller to dial frequencies, freezing on the signal. Since the scanner has an automatic function (Auto squelch) to be silent when there's no signal and only make sound when there is a signal, this isn't very difficult to do.
The audio is sent to speech recognition software, and if something intelligible comes out it listens and logs what it hears. If there is nothing intelligible there, it tells the controller to keep dialing. Alternatively it could listen for digital transmissions and attempt to decode what digital mode it is in, and log the output of that.
There's no end to the things I could do with this thing, but primarily I intend to have the logs written to the root window of my desktop, creating a cool effect that will earn me geek points like crazy. =)
Attacking number stations to unveil matters of national security is just a side-project. Eheh.

(Please note that I'm X-posting this, but I'll still be checking both groups for replies so feel free to post to only one of them.)

Yep. Used to go for the Kirkland units at just about that price; they disappeared from our local Costco a few years back. I'm thinking their Duracells are right around that price too, but (1) I don't buy Duracells and (2) that's over 50 cents per battery when I can get 30 Ray-O-Vacs for $9.99 any day of the week at Menard's. Sometimes even better at Menard's; the last batch of AAs I bought were 12 for $2.59 with a $2 rebate on up to two packs, or just under a nickel per Ray-O-Vac.

Back when I got the Kirklands regularly, they were about half the cost of the name brands I was finding and had a little better than half the lifetime, not a bad deal at all.

I own a Heathkit IP-17 which had identical rating to the HP-23 that you have. For higher amounts of current, I cobbled together the combination of a Variac, a salvaged TV set power transformer, bridge rectifier, and filter capacitors to do the job.

Although unregulated, it performed its job well for many years.

Sorenson and other firms manufacture large, regulated power supplies that will do arguably better work, but even used these generally command a price of several hundred dollar, compared to the $30 or so that I invested in my home built variable voltage supply.

Try periodically checking on eBay.

Good luck. Harry C.

Hello all,

I just got a Trio TS-780, however there is no RF power on Transmit. At first i thought that PA stage was damaged however i also noticed that the ON AIR Led and Antenna Switch are not energised in Transmit Mode. Receiver is working perfrectly. Can anyone supply me with detailed schematics for this Transciever and whether anyone has seen this fault on similar transceivers?

Thanks

Mario

A common lightning protection technique used in many commercial radio stations is simply to wind maybe 50 turn of the coax around a 6 or 8" carpet tube or PVC pipe, then ground the shield on the coax as it leaves the bottom of the coil. Often but not always we would put a spark gap to ground at the top of our so called "lightning choke". A similar technique was employed to protect the "sampling loop" coax feeders. The only thing that we used transformer lightning isolation for was the tower lighting circuits (our tower lighting transformers were large guys of conventional core construction, but with the secondary winding isolated by about about 2" of air spacing in all directions).

Each of our 4 225-ft towers sat on an insulator to isolate them from ground, with a spark 1/4-inch spacing spark gap with two massive 2" balls connected to the ground system. The only problem that we ever had with this setup was that in the summer, occasionaly a large insect would venture into one of the spark gaps and be instantly carbonized by the r.f. being transmitted -- triggering automatic shutdown of the transmitter in the process. When this happened, one of the operating engineers would have to divine which of the four towers was shorted, then fly like lightning itself with a flat file in hand to the tower and clear the problem (while hoping that no one would take it upon themselves to reset the transmitter while he was making repairs)!

Ahh, the fun days (NOT)!

There have been a few threads recently about regulated tube supplies,
and each time I see them, I keep wanting to post "but most supplies in
the days of tubes were not regulated".

It's almost as if people have lost that fact, so used to solid state
where regulation is the norm, though regulation there often means
a different thing. Now it's used to get a low impedance out of the power
supply, or because the devices are finicky over a wide range of voltages (or
outright can be damaged by too much voltage, as in the case of ttl). Of
course, three terminal regulators made it easy to add regulation to
just about any sold state design decades ago.

But of course, for most consumer equipment there were no regulators (though
that may mean little since there was little consumer electronics around
the house up till about forty years ago) If there was regulation it
was a VR tube, and for a specific stage or stages, liked an oscillator
stage that would change frequency with voltage variation, rather than making
the whole supply regulated.

It was in the lab that most regulated supplies were seen. All that
test equipment is a prime example. You wanted reproduceability for
that DC coupled scope, so you'd want it well regulated.

I guess in the lab you'd see variable voltage regulated supplies but
that would have been the key place.

Michael, excellent point all.

Years back I used Lambda regulated H.V. supplies in the workplace, but only for critical application in experimental physics apparatus where the accuracy and stability of the voltage had an important impact on our research. (I still own a comercially produced 0-5 Kv regulated supply, whose use is largely limited to powering photomultiplier tubes used in nuclear research applications.)

Like you, I don't recall voltage regulation ever playing a significant role in vacuum tube electronics, except for those instance that you mention using VR tubes (as in my Hallicrafters SX-71 receiver to stabilize the local oscillator). Still, stabilizing that sucker required much more effort than simpy a VR tube!

Sadly, I gave away the original Variac adjustable power supply to a student that had greater need for it than myslef. Then too, very little of the vacuum tube work I do today requires more than a few mils which My Heatkit IP-17 supplies.

Kindest regards, Harry C.

Mario -

Always have a 50 ohm dummy load attached for testing.

Check the T/R (Transmit/Receive) relay in the RF section of the radio.
Is it working?

Well, it's a mystery. There is no manufacturer's name on it anywhere. And
all the parts are from various well-known parts vendors (except no labels
on the coils). There are several theories:
Might be a home-built set - if so, it's incredibly well done, including
an engraved front panel
Might be built from a kit - but then you'd think the kit manufacturer
would have put a name on it somewhere.
Might be a factory-built set for some department-store chain that was
to attach their own brand label, tho there is no evidence that one
ever was attached.
Might be a factory-built set and the maker is deliberately non-identified
to avoid paying royalties on the Neutrodyne patents. Which could also
apply to a kit. I read some early superhets were sold as kits to get
around paying patent royalties.
Someone suggested a fly-by-night manufacturer, who would come into a
village with a wagon load of receivers, and secretly bring another
wagon with a transmitter. The transmitter would assure they had a
good signal while they were selling the receivers; and once they were
all sold they could move on. However this receiver is certainly not
shoddily constructed.

Any other theories?

The dials are not calibrated in frequency or wavelength. They look like
National vernier dials, calibrated 0-100.

5090. 1936 vintage rig

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-11 13:47:14 UTC
From: MadEngineer <glenn.b.dixon@gmail.com>
Message-ID: <1131716834.266593.323410@f14g2000cwb.googlegroups.com>
Source record: 16373

Hi All,

My father, W7GEG, got his ticket in 1936 when he was in high school. Like many others, he built his first rig. His transmitter was based on an 809 tube and had plug-in coils to switch bands. His receiver was a three-tube regenerative, but he doesn't remember the tube types. He worked mainly 40 meters. According to my dad, both designs were very popular at the time.

The rig worked the first time, and was a thrilling experience for him. "I probably wouldn't have gone into a technical career had the radio not worked," he told me. He holds a PhD in physics.

Can any old-timers out there help me with any information regarding what he might have built? I thought I might try to either find or build a similar rig as a gift, or at least present him with the plans the equipment was based on.

Thanks, 73,
Glenn Dixon AC7ZN

5091. FAQ, just what is Ham Radio?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-11 14:38:23 UTC
From: Polymath <aiyr.r.bean@lycos.co.uk>
Message-ID: <1131719903.005850.10610@g14g2000cwa.googlegroups.com>
Source record: 16374
Cross-posted to: uk.radio.amateur,rec.radio.amateur.policy,rec.radio.amateur.homebrew

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B

licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

I'm Not really an old timer yet :) but you can get the complete
QST's from 1930-1939 on CDROM from the ARRL. That'll
be a nice gift, Im sure there
are plans in there to build a similar rig..

I thought Guinness was the drink of the Irish... I personally cant stand the stuff, surely its a "nice cup of tea"... Steak and Kidney is Rank...Much better mince beef and onion, or chicken and mushroom where it comes to pies... As for fine cars?? that surely is sarcasm ;o) .... "you have learned well young Jedi"...

> Nick - Who actually likes the people living that side of the pond.

Messed about with?? normally they come in chunks of pure cut steak but the
kidney... uuurgh.. hate it in any shape or form. If your speaking from
experience you must have visited some really dodgy restaurants while you
were over here. As far as salads go.. they arent cooked they are simply
washed and put on the plate. Fancy boiling a salad.. lol...
Graham... who also likes "most" Americans ;o)

Guiness is NOT a UK drink... those Irish folk invented that, begorrah!

The UK national drink is tea , made with milk, hot water (and tea of course)... none of the iced tea you Texans seem to like. :-)

Steak and kidney pie is actually better washed down with one of the Aussie lagers!

Southern Ireland isnt. And most of Northern Ireland would disagree too....

5103. Call for Entries: Home Meadmakers Competition, Feb 2006 IMA Meadfest

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-11 21:56:36 UTC
From: Oskaar <oskaar@gotmead.com>
Message-ID: <ns8df.5671$Vw5.5321@fe04.news.easynews.com>
Source record: 16386

Hi All,

I'm posting this in this brewing group because I know that there are many brewers who also make wine and mead.

I'm looking to get an idea of how many people are planning on entering the competition. Please let us know if you'll be entering any meads. As mentioned above the meads will be judged by commercial mead makers, BJCP certifed Judges and other mead-centric folks.

The competition is Feb. 10 - 11 2006 in Boulder, CO.

If you have questions about the competition or are uncertain about how to enter, this is the place to find out.

For more information go to:

http://www.meadfest.com

Thanks for your time and consideration

Oskaar, your friendly Home Meadmaker Competition Committee Chairman

This reminds me of a funny story:

Once upon a time there was a retired amateur going on a DX-pedition to the South Seas in the spring of '78 who set up his equipment and started operating... unfortunately a terrorist group decided he was an worthwhile target and overran his station. Last thing we heard on SSB was W4<garble> calling Mayday, Mayday, Mayday! <hiss> <static>. A few weeks later a forensics team found nothing but charred wood and bones. The leader of the team reported back to the coroner: "Looks like an old southern ham got roasted at Easter".

Warm beer sucks, but throughout history that is the way it has always been
consumed.
I like the people living on that side of the pond. Have they done something
personal to you that you hate an entire country?

I don't know what a "real amateur" is and I, for one, have never
claimed to be such.

However, after a number of years of contributing to Usenet under
my own name and callsign, my family was subjected to malicious
and threatening letters sent by Stephen G Bryan G0SGB in 1998,
a matter for which the plods were involved.

His criminal activities followed on from an abusive, insulting,
infantile
and obsessive tirade by him in this NG, seemingly because he was
intolerant of those who disagreed with his CBers' activity of WABbing.

Such threatening behaviour drives one underground, and also serves
to illustrate, perhaps, the difference between a _REAL_ Radio Ham
and a CBer-Masquerading-As-A-Radio-Ham?

I don't have a problem with shame or embarrassment, I'm quite shameless and I'm only embarrassed while during my carrier detector diode into a heat emitting diode :)

But seriously, I think it a very bad idea for the FCC to continue to publish names and addresses of licensed hams. Especially if a predator ham develops a taste for minors. That, by the way, is now one good reason to ban minors from having ham licenses... for thier own safety. Sorry kids.

The Eternal Squire

5111. FAQ, just what is Ham Radio?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-12 02:32:54 UTC
From: eternalsquire@comcast.net
Message-ID: <1131762774.584136.56120@o13g2000cwo.googlegroups.com>
Source record: 16394

Amateur Radio Frequently Asked Questions:

1) What is Amateur Radio?

In its most general sense the term Amateur Radio covers a very wide range of activities initiated by a group of people for the public good both short term and long term on a purely non-profit and non-commercial basis, using frequencies provided by a nation upon which that group performs its activities. Such a group is known as a nation's Amateur Radio Service.

2) Why Amateur Radio?

A great many national governments recognize the necessity for forming a body of volunteers existing entirely outside the commerical telecommunications infrastructure who are permitted to use radio frequencies. The necessity comes out of at least the following motivations: (a) the ability to form auxillary communications for public safety and welfare less subject to regional outage in the face of disaster, unrest, or other emergencies affecting normal communications (b) encouraging spread of scientific and technological literacy throughout the population via self training, (c) encouraging innovation in the state of the art of communications technology or in the basic sciences on which that technology is based, (d) encouraging goodwill between countries through informal communications between citizens of those respective countries with no payments needing to be made to a common carrier.

3) Who is eligible to operate an Amateur Radio?

Typically any citizen of a country whose laws create an Amateur Radio Service, who can pass a skills test in any or all of theory, regulations, or telegraphy which may be required for the safe operation of an amateur station on the frequencies granted for such operation. The skills test is usually basic for minimum priviledges and intensive for maximum priviledges. The skills test is usually administered either by a government official or by a panel of volunteers appointed by that official. Upon passing the skills test a license to operate is granted to that citizen.

4) Can children operate an Amateur Radio?

In the United States and many other countries there is no minimum age requirement for a minor citizen to be licensed to operate an amateur radio.

5) Who is ineligible to operate an Amateur Radio?

Typically anyone ever convicted of a felony of any kind, although this bar can be waived on a case by case basis through a legal hearing. Also, typically anyone whose license grant to operate had been revoked through a substantial violation of that nation's amateur radio regulations, and again, this bar can be waived on a case by case basis through a legal hearing.

6) What equipment can be legally used for operation?

In most countries any licensed amateur radio operator can build equipment either directly from electronic components or may adapt existing telecommunications equipment to transceive on frequencies designated for amateur radio. In other, more authoritarian countries, equipment may be held in keeping by a nation's government in designated club buildings. In countries governed under a civil law framework rather than a common law framework, a one-time or periodic tax may need to be paid to the government for each transmitter or receiver to be authorized for use by that citizen.

7) How much power can be legally used for operation?

Each nation can choose maximum legal power either on the basis of license priviledge, propogation or interference characteristics of the band in question, or safety considerations such as bodily RF exposure. Power limits could range from 5 watts to 2000 watts.

8) What communications can be conducted over amateur radio?

Typically only communications relating to public safety, statements of a personal nature, or technical conversations. Further, personal conversations may not involve material considered obscene or indecent as based on the standards of the nation of whom the citizen is a part. More authoritarian countries may place additional restrictions such as the banning of any communications containing political content or opinion. Limited one way communications are permitted, usually pertaining to telegraphy practice or to call outs for the purpose of initiating a two way conversation. Communications may generally not be intentionally obscured or encrypted, any published or commonly utilized language or protocol is considered acceptable for this purpose. One-way continuous broadcasting of news or music is typically prohibited.

9) Can unlicensed people ever operate an amateur radio?

In limited cases, yes. a) In genuine emergencies dangerous to life or limb, or potentially so, unlicensed people may use the signals MAYDAY or PAN respectively to call out for help or to warn away on any radio frequency, not just amateur radio frequencies. b) Anyone can operate an amateur radio under the direct supervision of an amateur radio operator using the priviledges of that supervisor. c) Anyone can use a frequency for micropower use so long as the frequency is not expressedly prohibited for such use. Power limits can be quite severe but they are adequate for use in demonstration, education, or research and development within the home or laboratory.

It is a myth that any person can transmit or broadcast unlicensed in international waters. Typically jurisdiction banning unlicensed operation extends either through the flag of the vessel containing the radio, or through the citizenship of the person transmitting.

10) How is amateur radio different from other competing informal radio operation?

Some countries do authorize citizen, family, or remote control radio services restricted to the use of government type-accepted equipment having fixed frequency channels, limited power, limited antenna size and/or height, and limited maximum distance.

Amateur radio is distinguished from these services by virtue of its special characteristics: a) potentially unlimited range, b) no restrictions to type-accepted equipment, c) transmission may take place anywhere within the designated band, d) international communications are allowed.

11) How is amateur radio different from experimental radio?

Some nations do offer upon application a legal grant for a limited number of people to operate telegraphy, voice, or telemetry upon bands or frequencies having interesting characteristcs. These bands or frequencies may later become adopted as part of the bands authrorized for amateur operation.

12) Is there a banned countries list?

Not at present. During the Cold War the United States and some other democratic nations did indeed publish a short list of totalitarian states and other states sponsoring terrorism with whom there was no legitimate purpose other than espionage for international communications, even as amateur radio operators. Such blockades are no longer in force. Instead, amateurs may not communicate with private citizens of other countries who have an objection to amateur radio. For all practical purposes this means the only countries with whom amateur radio operators may not communicate with are North Korea or Yemen, as
those countries do not permit thier citizens to own or use an amateur radio.

Polymath, you have my profound apologies on behalf of the entire
worldwide ham community for the harm you have suffered. And as I just
said in a seperate thread, it is things like this that make me think
that while governments have a right to demand the addresses of licensed
hams, it no longer has the right to publish them. That goes *double*
for hams who happen to be minors... Sadly, depravity no longer limited
to any single walk of life, and anonymity on the net is an importand
safety measure that should now go hand in hand with exercising the
right to free speech.

<snippety>

You have the wrong newsgroup. Look at the group name once again
for a clue: rec.RADIO.AMATEUR.homebrew.

Homebrewing has a different meaning in the context of amateur
radio. It refers to the design and construction of radio or electronic
test equipment from scratch.

As much as I personally like mead, I can say with confidence that
you need to double-check your newsgroup names before you post.

Keep the peace(es).

Whoopsie!

Well, bring a homebrewed radio with you to the meadfest and I'll be happy
to pour you a glass of mead!

Anyone is welcome. Sorry for the off-topic post!

cheers,

Oskaar

Ahh, Joseph Lucas...the prince of darkness. The warm beer bit comes
from having Lucas also build refrigerators. I too have been the
victim of a string of British motorcars. Triumphs and Austins and the
odd Lotus. I even race-prepped them. I also get around to flying
aboard BAE-146s every once in a while. Just like British sports cars
they are. Fast enough, handles like a housefly, not all that
comfortable and as noisy as hell with the gates open.

well, if you had more than one transmitter, you could simply act as a
repeater and boost the signal on as many stations as you had transmitters.

but i just dont see it actually happening. sounds crazy.

What is this absurd fascination with Morse Code? Wouldnt you rather just
talk to people? I know all about the arguements about it getting through
when all else fails but is it really life and death?? If i cant get through
on the radio I use a Phone or the Internet. After all its just a hobby.
Besides, doesnt all that dot dot dot.. dash dash dash give you a headache
after a while??
Dont get me wrong, im not having a go at Amateurs im just asking the
question.. why is it so important?

Regards,
Graham

One thing you must take on board Poly is that these threats that anyone receives arent from just Amateurs/CB'ers. They are from people who use a radio just like they use forums.. to upset and bully people and to force their sometimes vile views upon people. These people are in both Amateur and CB circles. Its not a CB fault, its down pure and simply to "nut jobs" which the majority of CB'ers and Amateurs arent. Unfortunately if you take a stand against these people and your personal info is easily available for these nut jobs then im afraid sometimes you will get threats upon yourself. Just because you post your replys with merely a "Handle" or first name doesnt mean your a cowering hiding lowlife, quite often its because people dont wish to have this s_it from nut jobs thrust upon them. You can still make a valid point without using your traceable details. I know you shouldnt have to worry about such things but we live in the real world. As for the nut jobs... sometimes simply ignoring them is the best thing to do. They crave the attention. If you dont give them the attention they move on. Whatever you say to them they will never change.....

Dana <dana@panix.com> wrote:

> The mistake the FCC made was dropping the code requirment down to 5 wpm.
> Lots of nivices squeeked under the wire.

the mistake every authority has made is....

when you cheapen a licence , you get lower standards of behaviour being
displayed by the licensees.

when those who have licences did very little to get that licence they will
treat that licence with very little respect.

when those licensees are governed by rules/regulations then their
behaviour may well become the subject of complaints.

complaints must be investigated.
this costs money.

end result....
lowering the 'cost of administration' allows cb'ers onto amateur bands.
cb'ers on amateur bands will cause problems.
problems cause complaints.
complaints cause investigations.
investigations cost money.
money that was hoped to have been saved in the first place !!

and a lot of this behaviour can be put down to ONE THING.
(even the interview with an rsgb president on the arrl website shows this)

the plan to get rid of compulsory morse testing for hf access.

Then can you explain it to me then? Im not being flippant, I actually want to know why its important and why, in your words, it drops the quality of people who chose to become Amateur if they don't do morse... why does it make them any less of a good Amateur?... and why do you think that because morse might be dropped the band will become full of CB people who will wreak havoc? And why do you class all CB'ers as the same?

Yesss! The lightning choke! An idea that even has intuitive appeal to me, and I have already gotten some pipes to wind one on (and weatherize it too).

Even w/o a dedicated grounding on the "cold" side, it has the effect of slowing the rise and giving the spark gap more time to work on the bolt energy.

Chokes are even available commercially, and are used a lot in animal concentration camps (well, make that on electrified cattle fences).

See
http://www.kencove.com/ShopDetail.php?recordID=MWLA
and
http://www.kencove.com/ShopDetail.php?recordID=MLC.

Now off to buy some CRT high voltage wire for the DC grounding / DC block wideband transformer.

all you have to do is observe the behaviour on this newsgroup.

the outrageous foul language used.

and then listen to 40m

by even attempting to do the morse test shows an attempt and willingness
to improve.
something that 2500 showed they didnt have when they ran away.

and worse... they showed it to the authorities.

and they will continue to get 'trashy'

if 'u' are given a licence for almost no-effort then that licence is
worthless because when lost ..it represents no-amount of effort.

Lol, great command of the English language there. I wonder if his morse is as bad........

> the mistake every authority has made is....
>
> when you cheapen a licence , you get lower standards of behaviour being
> displayed by the licensees.

I disagree. There might be one or two idiots but that doesnt fall completely at the ease of getting the licence.

> when those who have licences did very little to get that licence they will
> treat that licence with very little respect.

Once again, after showing a willingness to actually bother to get licenced, being it easy or not, they have to purchase the said equipment. Surely your not saying CB'ers who dont give a rats ass about Amateur are spending their hard earnt? money on Amateur kit, and getting registered so you can find out who and where they are... just to mess about and upset a few advanced Amateurs? Seems a very strange way of going about things.

Surely these idiot users are more likely the completely unlicenced users on stolen radios or kids messing about on parents radios while they are out rather than someone who wants to become a "first step" Amateur? Also quite a few people who gain M3 licences or whatever the equivelent in the US surely would go on to intermediate and so on rather than just stop there. A few will yes but many will want to progress.

> when those licensees are governed by rules/regulations then their
> behaviour may well become the subject of complaints.

Or maybe not....... your now trying to say Amateurs above the entry level never cause interference or mess about sometimes on the air.... b-ll-cks.

> complaints must be investigated.
> this costs money.

yes........

> end result....
> lowering the 'cost of administration' allows cb'ers onto amateur bands.

Err, whats wrong with CBers becoming radio Amateurs? Its happened for years and years....long before the licence was made easier. And most of them became perfectly respected Amateurs.

> cb'ers on amateur bands will cause problems.

NO....idiots on Amateur bands will cause problems. Or do you tar all CB radio users with the same brush?

> problems cause complaints.

Yes.........

> complaints cause investigations.

Yes............

> investigations cost money.

Yes......

> money that was hoped to have been saved in the first place !!

Saved for what? The fully licenced Annual Amateur Jamboree ?

> and a lot of this behaviour can be put down to ONE THING.
> (even the interview with an rsgb president on the arrl website shows this)

Oh in that case it must be right then.....

> the plan to get rid of compulsory morse testing for hf access.

For gods sake... morse isnt the "be all and end all of radio", its an old out-dated form of communication which had its use in the past but is now just a form of elitist snobbery. Also trying to say anyone who doesnt want to learn morse is basically a "scumbag" shows Bigotry beyond contempt. Why not welcome the new Amateurs and encorage them to advance rather than look down on them. The licence was made easier because the userbase of Amateur was drastically on the decline. It was done to encorage more people to get involved and keep the "hobby" alive.

Paul Kearney EI7GM aka Rumpelstilskin, google for more, a search by
"pkearn", a segment of his mail address used most frequently is most
effective.
Be warned, boredom may set in rather quickly....

Hello Greg,

Thanks for your reply. I have just downloaded the user and service
manual for the TS-780..i will give it a look later on. However as for
T/R switch...i don't think it is being activated on trasmit as i don't
hear any replay operation. So it seems that part of the control
circuit is not functioning. I still have to look at the schematics
though.

Thanks for you help

Mario

Has the wiring in the microphone been checked? Maybe it's simply a
broken PTT line inside the mic or at the connector end...

Hi Scott,

Yeah it has been checked and it was found to be correct. The TS-780 also has a Send/Rec Switch on the front panel and when it is flicked in Send Mode, it goes in transmit mode (no reception is possible) however ON AIR LED does not switch on, T/R relay not activated and no RF power output. Furthermore, i believe that when TX offset is activated, the display frequency should change (depedning on the offset frequency) on transmit. However this does not change. It seems that in transmit mode, the transmitter is not being activated at all.....that is why i presume its a control failure rather than RF or final stage failure. I am currently following the logic control circuit to switch between transmit/receive mode.

Thanks for your help though. If anybody has more suggestions, please let me know. Thanks all

Mario

No problem!! I just wanted to make sure the simple stuff was ruled out
first =8O

Sounds like you're on the right track. Assuming you have a schematic,
just start following the PTT line from the mic jack until you hit a
logic gate or a transistor. One of those is likely to be used as a
switch that routes some DC voltage to the tx circuits and maybe labeled
something like T9V or TX9, indicating some voltage level for TX mode.
Once you find the (probably a transistor) device being used as the power
switch for the transmit sections, check the capacitors and resistors
connected to it for shorts or opens. Is it possible there are 2 power
supply sections and one side (transmit) is dead?

yes... wallyrally has been hiding in the shadows for over a year.

he/she/it refuses to identify himself when challenged to do so but
will publish the name and callsign of other(s) multiple times.

one wonders if he/she/it has some unfortunate status that is
best kept out of the way. a srarus that will explain his/her/its
attitude towards those who have the courage not to hide when
posting on this newsgroup.

he/she/it has criticised the spelling and grammar of other(s) but
conveniently ignores the historical catalogue of spelling mistakes
that he/she/it has made in the past !!

That comment was meant for the posters who say people on Amateur Bands who do not wish to involve themselves with morse are lowly class CBers who seem to live in trailor parks and live off welfare and care nothing (scumbags in other words) It wasnt aimed directly at you it was put in as an "Also" to those who try to put that image over. Maybe I should have made it a bit clearer.

Does anybody have a source for the DV2840S MOSFET or a DV1007 (same thing, old part number)? Tried Google and Dogpile. Found one place had them for $30 each. Can anybody find a cross reference to an ECG or NTE part number? Tried both online, with no results. How about an equivalent part??

It is for a 2M amplifier project from the RSGB book "VHF UHF Manual"

Scott,

Have you tried RF Parts?
"Best place in US for the solid-state amplifier builder
They should be able to find a suitable cross reference to a Motorola,
Toshiba or Mitsubishi device
http://www.rfparts.com/mototran.html

RF Power MOSFETs - N Channel
http://www.rfparts.com/transistorspecs.html#mosfets

Transistor Case styles
http://www.rfparts.com/trancase.html

BTW, $30 is a correct "ballpark" price for a MOSFET in the 2-meter range (up
to 175 MHz) with 70 watts output at 12.5 VDC

Scott,

Why don't you look at the 875A kit from CCI.
http://www.communication-concepts.com/875a.htm

You can purchase it as an entire kit, or juts what you need.
Based upon the Motorola Application Notes of Helge Granberg, K7ES (sk)

Its an all-purpose amplifier book and covers up into VHF and microwave.
It is a collection of previously published articles as opposed to a
book on its own.
Thats not necessarily a bad thing if you don't have the past 20 years of
QST and QEX handy.

-Bill

Thats at least a 25 year old part and not common then. If RF Parts
doesn't have it it's likely unobtainium.

RF Parts is the first place I went. I didn't see that FET listed.
Seems to me I found a website that listed an SK number cross reference,
but I can't find it again. I did email RF Parts with that SK number and
it was $2.40, so I think that SK number was referring to some other FET
on that website...They told me they were unable to give me any info on
that part when I asked if it was a MOSFET...

Both the transmitter and receiver are "classic" designs that survived (with variations) from the 1930's through at least the 1960's ARRL handbooks. I don't think you'll find an exact copy of what he built because most of these rigs were truly homebrewed out of what was available at the time.

By the 50's and 60's most single-tube transmitters didn't use triodes like the 809 but used tetrodes like the 1625, the 6146, sweep tubes, etc. But the principle is the same.

A three-tube regenerative was a very long-lived design as well, Allied sold their "Space Spanner" and "Ocean Hopper" up through the 1960's I think, maybe even the early 70's. A google for "three-tube regenerative" shows up several in this vein using 30's era tubes, for example:

5177. Question on Drake TR-4 restoration project.

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-14 17:05:25 UTC
From: Paul P <p.pinyotREMOVE@REMOVEworldnet.attREMOVE.netREMOVE>
Message-ID: <pt3ef.54842$qk4.47952@bgtnsc05-news.ops.worldnet.att.net>
Source record: 16210

Gents,

I have acquired a Drake TR4 with power supply that track accurately on 80, 40, 20, 15 meters. The dial on the three 10 meter bands indicates about 30khz higher than actual. I have tried to adjust the touchy L2 accurately, looked at T1 for problems and swapped V1 tube. There are no cracked ferrite cores. Other hams on the air have told me this is typical of this TR-4 gear on 10 meters.

Is there a component or gimmick that would bring the 10m tracking back on? Does having the 6JB8 PAs screen and plate B+ disconnected affect the 10m band in this way (I would think not)?

What am I overlooking?

Thanks,
Paul.

IT IS MY OPINION THAT...
theres a difference between
a cb'er who choses to join and amateur radio to improve his/her knowledge
and capability with radio
and
a cb'er who choses to invade amateur bands just to have extra bands to
play with and brings his/her 11m habits with him/her

Paul -

A frequency counter could quickly diagnose this issue. Have you checked the
crystals? The LMO may be working correctly.

I'm firing off a reply before I get the schematic D/l from Bama but this reminds me of a problem I had with my old HX-50A.

I wouldn't be quick to blame all 3 band xtals to just go bad in the same way...and it would seem that the LMO is ok. But my old Hammarlund had a common coil in the osc ckt that when mal-adjusted pulled the 10m xtal freqs WAY out of whack.

Food for thought. Its hard to find a TR-3/4 anymore that hasn't been subjected to attempts to put it on 11 meters and the 10 meter alignment has been goofed up.

And the funny thing is, at a high load such as my GPS III+, those alkalines
with their capacity diminished by the high current draw still last longer
than the NiMH that supposedly like high current draw. (I said the NiMH
compare favorably, not that they outlast alkalines.) I agree with you,
I've been playing aloud with numbers that don't always belong in the
same arena. And too many other factors impinge; I save money using the
NiMH in the GPS, but I'd kill them in flashlights that I routinely
leave on and forget. And then there are those sulfated wet-cell batteries
in the garage... *sigh*

It sounds to me lile your oscillator might be misadjusted such that it is oscilalting on the fundament rather than the 3rd overtone. If you are lucky just tweaking the oscillator coil will snap it back to where it belongs. As the other guy pointed out, though, the oscillator might have been monkeyed with if some CB'er tried to modify it.

Also there is a better source for the TR4 manual, with better schematics. Look for TR-4C_Manual.pdf on Google.

What a small world, Harry. I was a field engineer for 25 years working mostly on Gamma Cameras. I sold a business a few years ago that primarily retrofitted Nuclear Medicine Gamma Cameras. I heard that there was a man in the Chicago area who set up a photomultiplier tube to track the moon for EME. I never found out his name, but probably could, if I made an effort. Are you a physics professor?

Cordially,
west

==========
I had the same experience with my ancient Garmin GPS 40 ;alkaline batts held
longer than NiMHs.
Possible reason is that alkalines cells are 1.5 V and NiMHs 1.2 V
It is well possible that although the NiMHs are only considered discharged
when the voltage has dropped to below 1 Volt (per cell) this voltage (or its
multiple) is too low for the GPS to operate, whereas alkalines hold a higher
voltage for a longer period.
I noticed that when the GPS switched itself off when using NiMH batteries
,the cells apparently were not fully discharged.
Using an automatic NiCad /NiMH charger operating with an initial discharge
period as part of the overall cycle,
it took quite a while ,before the NiMH cells were discharged before charging
commenced.

Whish is firmly where the responsibility is meant to lay. The Licensee is
the one responsible for the correct operation of his station at all times.
If he is not physically present, it is his/her responsibilty to ensure that
the equipment is disabled.

Yes, I agree with you whole heartedly but many older Hams refer to "both" as simply CB'ers. This "will" upset genuine CB radio operators, and those who did advance to Amateur from CB, as many full licence Hams dont seem able to distinguish between the two, or dont want to distinguish... thats the problem.
Also the point still stands that a few, if not lot of problems on Amateur bands could be down to kids going on their parents equipment while they are out. There are lots of possibilitys but the CB'er gets it in the neck all the time.

Not absolutely correct. Correct in some instances but i know lots of people
on 11 meter who go on SSB (illegaly of course) who treat it sensibly and
dont mess about. Many 11 meter users, especially the SSB users, have
reasonably good control on the airwaves even to the point of writing a log
and QSL'ing. These are CB'ers im talking about by the way, not Amateurs
although I know a couple of Amateurs who used to join in occasionally (using
their pirate call signs of course)

Maybe not to the point of disconnecting his/her equipment but at least
bringing up their kids to be respectful of things. I would personally put a
lock on the "shack" door so I could secure the room but some people have
them in their living room so sometimes I guess its asking for trouble. My CB
is in my office and also one in my repair "shack" and when I go out I make
sure both are locked. If I can do it for CB why cant they do it with their
Amateur kit... which is far more valuable in any case. Mind you, some adults
cant even be arsed to secure their guns but thats a different story.......

not exactly or only in theory the Ham is responible for the use of his
equipement, but when was the last time the FCC tried to bust a ham for
say someone breaking into his car and using the equipment

In addition some modes can be used without the ham being present at
all

My car for example will transmit an APRS signal at intervals anytime
the engine is running, unless I turn it off each time I turn on the
engine. This allows me to kow where the body thing is if my old man
calls back to house and tells me he is lost, or if I found the car
missing and knew none of had it I could tell the cops where to go find
the theives

That's a common myth. Neither type has a constant voltage during discharge, but the NiMH is much more constant than alkaline. Try this experiment: Put a resistor across an alkaline cell to simulate roughly the load a GPS receiver would present. With a DVM, check the voltage every half hour or so, and continue until it reaches 0.8 - 0.9 volts, which is where it'll be when nearly all its energy is gone. You'll find that the "1.5" volt alkaline cell voltage will reach 1.25 volts (about the voltage of a NiMH cell for most of its discharge period) at a point where half or more of the cell's energy still remains. That is, the cell voltage will be below 1.25 volts for half or more of its life. If you repeat the test with a NiMH cell, you'll find that the cell voltage is 1.2 - 1.25 volts for nearly the whole discharge cycle. So for about half the time, the NiMH cell will have a higher voltage than the alkaline.

Or, you could do it the easy way and look at the curves supplied by the manufacturers. They're readily available on the web.

If a device quits working at a cell voltage of 1.0 volts, you'll get nearly all the energy from a NiMH cell, but you'll be throwing away an alkaline cell that still contains a significant amount of energy.

> I noticed that when the GPS switched itself off when using NiMH batteries
> ,the cells apparently were not fully discharged.
> Using an automatic NiCad /NiMH charger operating with an initial discharge
> period as part of the overall cycle,
> it took quite a while ,before the NiMH cells were discharged before charging
> commenced.

Sounds like something was wrong with the GPS. If there was signficant energy left in the NiMH cells, it quit at a voltage greater than 1.0 volt/cell. And if it did that when using alkaline cells, you'd be throwing away an even bigger fraction of its total energy than with a NiMH cell.

There are several reasons why NiMH cells might not do as well as they should. One is that chargers will often shut down well before the cells

are fully charged. This is particularly common with new NiMH cells, until they've been cycled a half dozen times or so. Another potential problem is voltage depression, mistakenly called "memory". This can be cured by a full discharge to 1.0 volt/cell then recharge. Cells also have less capacity after long storage or a history of light use and recharge. Several cycles are necessary to restore full capacity. And of course, modern NiMH cells at 2500 mAh or more have a lot more capacity than earlier ones which were as little as 1300 mAh or so -- if you did a comparison some time ago, things have changed since. A number of fast chargers don't charge cells to their full capacity. Finally, a substantial portion of some cells' capacity originates in the marketing department -- tests I've run show the capacity of some to be pretty badly inflated (Lenmar is a common brand that comes to mind). They do take some care and feeding -- if it's too much of a hassle, alkaline cells are a solution.

Since when has the FCC had jurisdiction over radio amateurs in the UK?
British regulations are different to that in the UK.

Hello All,
I picked up a really nice working Swan 350 at a hamfest this past weekend. I bought it for nostalgic reasons as it was the kind of rig my dad bought for me in 1965. I need info on how to fix the infamous "Swan drift problem". Anyone have any websites I can go to get mods for this rig including the drift fix?
Any help will be appreciated!

Steve W4SEF

Hello,
you might add a "Huff and Puff" stabiliser.
It is a very good and simple system to lock a vfo in 10Hz or larger steps.
The original is made by PA0KSB.
Just google and read..

Roy ,Tnx for your comments ; I'll do some tests with NiMH cells
using a 'Maha C777Plus' discharger/(pulse)charger and check capacity .
I'll repeat the discharge/charge process a few times to see whether capacity
changes.
I realise that automatic chargers charging at a high current might not
charge any cell to its maximum capacity,
that's why I shall also charge the cell at a lower rate using a LM317
constant current circuit.
with the Maha device the cell's capacity is indicated following the
completion of a discharge period from fully charged to a threshold of just
below 1 Volt
I knew that brand new cells only get their full capacity after having been
cycled a number of times.
BTW : NiCads and NiMHs I use regularly are kept in good condition by
constant trickle charging at a few mA
, again ,with a LM317 constant current circuit ,because specially NiMH cells
have a relatively high self-discharge rate.

The problem is, for the most part, lack of proper temperature compensation. Sure, the voltage regulation isn't that great, but it's not the main problem.

Looking at the diagram for the VFO you can see the tuned circuit components. You can add a negative temperature coefficient capacitor to the circuit to compensate for the (usually) positive coefficients of the parts.

I did this successfully in a Viking Valiant. I reduced the drift from about 10kHz or more on 10 meters to about 1kHz. One thing I did was move a hot resistor out of the VFO compartment to reduce the amount of temperature rise of the critical parts.

You can also leave the unit on, at least the VFO, at all times so the temperature will be more stable.

Ah yes the famous 3-drifty. I wonder if they had a temp compensation
adjustment. Consists of one positive and one negative coeficient fixed
cap of the same value, each one tied to one side of a differencial
trimmer cap, the other side of each cap tied to the tuned circuit.
You then adjust the variable trimmer for the least drift.

Bob,

can you tell me what part of the circuit needs the negative cof cap
and what value you think would be best?

Thank you for the help!!

Steve

Steve,

I don't have the circuit diagram so I can't advise. But across the inductor is the first place I would try. Of course you will have to reduce any other capacitors by that amount so that the circuit will resonate at the same frequency as before.

As someone suggested, a differential arrangement will work but it's a bit tricky. I'd prefer to substitute various values until I hit one that is close enough.

Bob

It can be hard to get a differential capacitor these days.

One alternative could be to add a varactor (and a series capacitor)
into the resonant circuit and vary the varactor control voltage
according to the temperature. A suitable NTC or PTC in the voltage
divider feeding the varactor could be used.

I built a single tube regen using a #19 tube from plans
in a book sold by Lindsay books (www.lindsaybks.com). It's
a surprisingly sensitive radio (using my GAP Titan antenna).
You do need 'phones to hear anything, but I suppose I could have
added an output stage to drive a speaker (maybe using a #33
pentode tube). BTW the #19 is a dual triode, so this radio
is the equal of a two tube set.

5219. Confused on diplexer issue.

I am confused on some issue of a diplexer. Sometimes,people say that
it is a device which used to split the signal from one source to two
loads i.e., it is used to split the signal from a dual band transmitter
fed on the same coax to two different antennas. Somtimes, they say
that it is the device that used to combine the 2 signals from two
different antennas to one receiver. Which one is correct?
Are they the same device?

5220. Re: Confused on diplexer issue.

Many can be used either way. The ones that are made of low and high pass filters are usually bidirectional and it does not mater which way they are hooked up.

Can anyone tell me how to create the HEX code for the 27C16 EPROM in the VHF Standard GX3000 64CH radio, or can anyone tell me where to find software to create the HEX file? I have an EPROM programmer that will program the 27C16 EPROM, so I just need a way to create the file. I would pay for the software or trade some of my radio manuals or radio software for it.

If you can get your hands on another radio of the exact same model you
could read it's EPROM -- most burners will do that.

If you happen to find something, please let me know as well! It
seems that, unfortunately, the original programmer for the GX3000 was a
custom unit that Standard designed specifically to work in conjunction
with their software, and their software does not export a binary image.

Happy hunting.

Thanks for the suggestion. Yes I can read another EPROM and copy it (I have done that) but I still can't change a frequency. I don't know how to convert the hex into a different frequency. It can be done. I have done it in the past but I lost the instructions on how to do it manually when we moved. From what I read on a few groups/boards there are hams who wrote software in BASIC which will do it automatically without all the calculations. I guess it is just a matter of the right ham to read the post :-) That's what I am hoping for anyway.

Ah. You didn't explain the real issue.

If you can't get anywhere with software, but you _can_ get your hands on
EPROMs from some different radios programmed to different frequencies
you will be able to read out their EPROMs into hex then compare the hex
files -- the different spots will almost certainly be where the
frequencies are different.

Whether you can figure out what it all _means_ is another matter,
particularly if Standard puts a checksum on their EPROM.

How facile a programmer are you?

Chances are that the Standard software outputs a file with some simple
format, which you may be able to reverse engineer with enough
perseverance. The Intel hex format is public domain, so once you know

what Standard's format is writing a translator would be fairly direct.

This kind of continual foul language, and the anti-M3 and anti-RSGB attitude (not to mention the "wisdom" portrayed in sig files) are some of the reasons why amateurs will not be taken seriously over the BPL issue. Do the regulars of this group realise that it is becoming legendary for everything Usenet was supposed not to be? Surely it is possible to have a civilised debate without this stuff?

It is an insecurity thing.

Look where the "and the anti-M3 and anti-RSGB attitude (not to mention the
"wisdom" portrayed in sig files) " comes from an you rarely see anything of
value from the same source.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B
licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their

intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

I am not that good :-) I have done as you suggested and got most of my frequencies but there are a few I don't have like a few reverse repeater pairs, ISS, and PCSAT. I was emailed a GWBasic program that is suppose to create the hex file for you. When I get time to enter the frequencies and burn an EPROM I will let you guys know if it worked. Thanks for your help Tim.

From: Amol Desai <gtg680m@mail.gatech.edu>
Message-ID: <dllrg1okl1@news-int.gatech.edu>
Source record: 16124

I'm looking to design and develop a remote controlled motor. The way i want to implement is to have a RF transmitter chip which will recieve digital inputs (pushbuttons) convert it to analog signal and the transmitter will then transmit the signal to RF receiver chip which will then convert it back to digital signal and send it to a PIC microcontroller (16f818, specs: 3V, 4MHz oscilator and 1 Mhz internal clock). The PIC microcontroller will then understand the signal and increase or decrease the speed of the motor accordingly. (Basically the concept is based on a remote control cars which kids play with).

I'm interested in knowing which kind (specs,brand etc) of RF receiver and transmitter chips can i use to work in this project. Obviously being a college student i would like to purchase cheap parts :) Any input will be higly appereciated.

> Can anyone help with the voltage and current rating of an old bridge
> rectifier - Westinghouse FC442?
> It's not listed in any of my data books.

Ron-

Does the equipment it came out of happen to have "FC" in it name? It could be a proprietary part made for that company. As such, Westinghouse would probably never reveal the specs to anyone else.

Could there be any other markings on the device? The FC442 might also be a form of date-code, such as 42nd week of 2004 or 1994, 1984, 1974, et cetera.

You may be able to determine a reverse breakdown voltage with a variable high-voltage power supply and a current-limiting resistor, but you may have to analyze the circuit it came out of for a minimum current rating.

Does the equipment happen to have service information available from some place like Howard W. Sams? If so, they often have cross-reference information for parts.

5243. Trickle Charge Battery

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-19 00:59:51 UTC
From: west <westley@tampabay.rr.com>
Message-ID: <bOuff.7515$bx3.4400@tornado.tampabay.rr.com>
Source record: 16126

I know this question has probably been beaten to death, nevertheless I hope you will still indulge me.

During a power outage, which occurs frequently in Florida, I would like to use a battery to power some communication gear. Although the battery is 12v and not 13.8v, I think that the gear will still work OK (hopefully).

Question 1. I believe that car batteries have a low internal resistance because their primary function is to provide a lot of current for a short time. There are other 12v large battery types that will last as long as a typical car battery. They are designed not to provide peak current, but to supply steady state current for a long time.
For the life of me, I can't remember the name of those type batteries so I can't do a google to find a supplier. I hope this is making some sense.

Question 2. Where can I find articles & schematics for a solar cell to provide a trickle charge for the aforementioned battery?

Thank you very much.

Cordially,
west

5244. Best FAQ in the Western Hemisphere

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-19 02:20:05 UTC
From: eternalsquire@comcast.net

Source record: 16127

Amateur Radio Frequently Asked Questions:

1) What is Amateur Radio?

In its most general sense the term Amateur Radio covers a very wide range of activities initiated by a group of people for the public good both short term and long term on a purely non-profit and non-commercial basis, using frequencies provided by a nation upon which that group performs its activities. Such a group is known as a nation's Amateur Radio Service.

2) Why Amateur Radio?

A great many national governments recognize the necessity for forming a body of volunteers existing entirely outside the commerical telecommunications infrastructure who are permitted to use radio frequencies. The necessity comes out of at least the following motivations: (a) the ability to form auxillary communications for public safety and welfare less subject to regional outage in the face of disaster, unrest, or other emergencies affecting normal communications (b) encouraging spread of scientific and technological literacy throughout the population via self training, (c) encouraging innovation in the state of the art of communications technology or in the basic sciences on which that technology is based, (d) encouraging goodwill between countries through informal communications between citizens of those respective countries with no payments needing to be made to a common carrier.

3) Who is eligible to operate an Amateur Radio?

Typically any citizen of a country whose laws create an Amateur Radio Service, who can pass a skills test in any or all of theory, regulations, or telegraphy which may be required for the safe operation of an amateur station on the frequencies granted for such operation. The skills test is usually basic for minimum priviledges and intensive for maximum priviledges. The skills test is usually administered either by a government official or by a panel of volunteers appointed by that official. Upon passing the skills test a license to operate is granted to that citizen.

4) Can children operate an Amateur Radio?

In the United States and many other countries there is no minimum age requirement for a minor citizen to be licensed to operate an amateur radio.

5) Who is ineligible to operate an Amateur Radio?

Typically anyone ever convicted of a felony of any kind, although this bar can be waived on a case by case basis through a legal hearing. Also, typically anyone whose license grant to operate had been revoked through a substantial violation of that nation's amateur radio regulations, and again, this bar can be waived on a case by case basis through a legal hearing.

6) What equipment can be legally used for operation?

In most countries any licensed amateur radio operator can build equipment either directly from electronic components or may adapt existing telecommunications equipment to transceive on frequencies designated for amateur radio. In other, more authoritarian countries, equipment may be held in keeping by a nation's government in designated club buildings. In countries governed under a civil law framework rather than a common law framework, a one-time or periodic tax may need to be paid to the government for each transmitter or receiver to be authorized for use by that citizen.

7) How much power can be legally used for operation?

Each nation can choose maximum legal power either on the basis of license priviledge, propogation or interference characteristics of the band in question, or safety considerations such as bodily RF exposure. Power limits could range from 5 watts to 2000 watts.

8) What communications can be conducted over amateur radio?

Typically only communications relating to public safety, statements of a personal nature, or technical conversations. Further, personal conversations may not involve material considered obscene or indecent as based on the standards of the nation of whom the citizen is a part. More authoritarian countries may place additional restrictions such as the banning of any communications containing political content or opinion. Limited one way communications are permitted, usually pertaining to telegraphy practice or to call outs for the purpose of initiating a two way conversation. Communications may generally not be intentionally obscured or encrypted, any published or commonly utilized language or protocol is considered acceptable for this purpose. One-way continuous broadcasting of news or music is typically prohibited.

9) Can unlicensed people ever operate an amateur radio?

In limited cases, yes. a) In genuine emergencies dangerous to life or limb, or potentially so, unlicensed people may use the signals MAYDAY or PANPAN respectively to call out for help or to warn away on any radio
frequency, not just amateur radio frequencies. b) Anyone can operate an amateur radio under the direct supervision of an amateur radio operator using the priviledges of that supervisor. c) Anyone can use a frequency for micropower use so long as the frequency is not expressedly prohibited for such use. Power limits can be quite severe but they are adequate for use in demonstration, education, or research

and development within the home or laboratory.

It is a myth that any person can transmit or broadcast unlicensed in international waters. Typically jurisdiction banning unlicensed operation extends either through the flag of the vessel containing the radio, or through the citizenship of the person transmitting.

10) How is amateur radio different from other competing informal radio operation?

Some countries do authorize citizen, family, or remote control radio services restricted to the use of government type-accepted equipment having fixed frequency channels, limited power, limited antenna size and/or height, and limited maximum distance.

Amateur radio is distinguished from these services by virtue of its special characteristics: a) potentially unlimited range, b) no restrictions to type-accepted equipment, c) transmission may take place anywhere within the designated band, d) international communications are allowed.

11) How is amateur radio different from experimental radio?

Some nations do offer upon application a legal grant for a limited number of people to operate telegraphy, voice, or telemetry upon bands or frequencies having interesting characteristcs. These bands or frequencies may later become adopted as part of the bands authrorized for amateur operation.

12) Is there a banned countries list?

Not at present. During the Cold War the United States and some other democratic nations did indeed publish a short list of totalitarian states and other states sponsoring terrorism with whom there was no legitimate purpose other than espionage for international communications, even as amateur radio operators. Such blockades are no longer in force. Instead, amateurs may not communicate with private citizens of other countries who have an objection to amateur radio. For all practical purposes this means the only country with whom amateur radio operators may not communicate with are North Korea or Yemen,
countries that are totalitarian states that do not permit amateur radio.

Better idea:

Get a pair of PC's each connected to a 2 meter HT through a TNC.
Program one of the PC's to take the ASCII data and translate that to
motor control, program the other PC to translate a keystroke to the
desired ASCII data.

Much cheaper.

The Eternal Squire

What you want is a deep cycle battery. Sometimes called a marine battery if
it is about the same size of a car battery. Used for trolling motors among
other things. Also used for powering golf carts.

5247. choke input voltage doubler?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-19 03:30:51 UTC
From: Ken Scharf <wa2mzeNOTTHIS@bellsouth.net>
Message-ID: <xZwff.7548$s92.5758@bignews6.bellsouth.net>
Source record: 16130

I was looking at some power supply circuits for
tube linears and was thinking about the full wave
voltage doubler. This is basicly two half wave
rectifiers in series. Now I could build this
circuit with a choke input filter for each half
wave rectifier of the voltage doubler, and I could
put the chokes in the lead without the rectifier.
In this case I could use one choke for both halfs
of the voltage doubler. The output should then
be about .9 * rms input voltage * 2
or 1.8 times the rms voltage of the transformer.

Has anybody ever tried this?

```

> diodes filter choke and capacitors.

If the choke is directly in series with the transformer, it will have to pass AC, and that won't provide normal choke input filtering (which steadies the DC current after the rectifier), but just puts an impedance between the transformer and the doubler.

There may be a way to incorporate an inductor into a doubler, but I don't think this is it.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B

licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

SOLDERSMOKE!
KL7R AND M0HBR PODCAST
FOR HOMEBREWERS!

Tired of listening to Led Zepplin or NPR on your I-Pod? Wouldn't you like to be able to carry with you the kinds of ham radio conversations that you listen to while in your radio shack?

Mike, KL7R in Juneau Alaska, and Bill, M0HBR in London, England meet regularly on the ECHOLINK system to discuss their homebrew radio projects. We have recently started recording these conversations, and are making them available as PODCASTS.

You can subscribe to the program, have them downloaded to your MP-3 player, and listen to them at your convenience.

To subscribe, just cut and paste this URL into your I-poder (or similar) software.

http://www.ourmedia.org/mediarss/user/36170

If you don't have an MP3 player you can just go to the site below and listen to the program using the audio software on your computer.

http://www.ourmedia.org/node/47682

We hope you enjoy the program. Please send us feedback.

> Question 2. Where can I find articles & schematics for a solar cell to
> provide a trickle charge for the aforementioned battery?
==========
1) If radio still works at 12 V you can use a 12 V battery

2)If a lead acid battery is charged to 13.8 V and subsequebtly discharged it still has 70 -80 % of its full charge when the voltage has dropped to 12.6 V.

3) The construction of car - versus leisure (deep cycle) batteries is that the plates of a car battery have a larger area but are thinner . This enables the chemical reaction to be stronger resulting in a high current capability (engine start) ,be it for a relatively short time. A leisure battery has thicker plates but with a smaller area ,hence these batteries can provide a more modest current ,but for a longer time .
Marine batteries have similar characteristics.
Leisure batteries are available as 'wet' units which can be topped up , with distilled or de-ionised water ,or are of the sealed type (as used in UPS =Uninterruptible Power Supply units and for example golf carts)
It is recommended by some manufacturers to charge SLAs = sealed lead acid batteries to 13.5 -13.8 V ,not higher ,when used for stand by service .
(I restrict the SLAs I use to 13.5 V)

4) If only a solar panel is used for charging a lead acid battery , a simple comparator circuit with any opamp ,sensing (a fraction of) the battery voltage against a zener reference can operate a relay disconnecting the battery from the solar panel and shorting the solar panel . Alternatively ,when battery is fully charged the generated current is dumped via a transistor - resistor or transistor- car bulb arrangement .
The current dumping system is necessary when other renewable energy sources are used as well ,like a wind generator. The latter system is the one I use .

Source record: 16138

You may be thinking of a "deep cycle battery", which make good batteries to power communication gear. They are commonly called 12 Volt batteries (just the same as car batteries are) but in reality, when fully charged, they are really 13.8 Volts (just as car batteries are), so they will work fine for powering gear designed for 13.8V.

Charging with a solar panel is pretty easy. All you need is a solar panel, a charge controller and the battery. The charge controller will have positive and negative connection points labeled "Array" or something similar. Hook up the solar panels positive and negative leads there (positive to positive and negative to negative). The other connection points will go to the battery (again, positive to positive and negative to negative). Aim the solar panel due South and tilt it (0 degrees being horizontal) at an angle that is your location's lattitude + 15 degrees. In Florida, that would be about 43 degrees in Central Florida. So the panel would be placed at a 43 degree angle up from horizontal and so that the solar cells are facing South. Be careful to have the batteries located in a place that is vented since they will give off a little hydrogen as they charge (even the sealed batteries do) and hydrogen is explosive (aka Hindenburg). A small vented box outside it good and run the wires inside (be sure to use a large enough wire to avoid dropping the voltage at the radio to a level that is too low to operate it). 10 or 12 gauge wire should be fine for short runs of 10 to 20 feet for an HF radio that draws something like 20 Amps in transmit.

More info on this can be found at http://www.homepower.com and I whole-heartedly suggest you subscribe if you are at all interested in alternative power sources for other things around the home. You might check your local library and see if they have the magazine (I can get it at my local Border's Book Store).

All chokes are in series with the transformer and pass some AC
component. If they only passed DC we would need them.

Without giving this too much (likely enought) thought I think this
will fail because without loads across -each- filter cap, the critical
inductance will not be obtained.

I was using DC in the "unidirectional current" sense, not the "having no AC components" sense.

> Without giving this too much (likely enought) thought I think this
> will fail because without loads across -each- filter cap, the critical
> inductance will not be obtained.

Regardless of the loads across the caps, this inductor cannot ever achieve critical inductance, since that is the inductance that keeps the current reaching zero, each half cycle. In this circuit, the inductor precedes the rectifiers, so its current must pass through zero twice per cycle, regardless of the capacitor load.

You could also put it in series with the primary, instead, and achieve the same effect (with the proper scaling to account for the turns ratio).

>>There may be a way to incorporate an inductor into a doubler, but I

Source record: 16141

So, why do you want to use a choke-input filter in the first place? AFAIK, they are most useful in giving you better output voltage regulation under varying load than a capacitor input filter. They have the added advantage that you can get more DC _power_ from a given transformer by using a choke input filter, because although the output voltage is lower, the RMS transformer winding current is lowered even more.

BUT--the voltage regulation advantage is lost if you try this with a half-wave rectifier circuit, because you cannot maintain constant enough current in the choke. To get the voltage regulation, the current in the choke must not drop to zero at any time in the cycle, and that's not going to happen while maintaining reasonable output voltage in a half-wave circuit. (There's some limited help if you put a "catch diode" to keep the voltage across the choke from swinging too far negative, but that's not enough to get the advantage of the full-wave circuit.)

In addition, as John says, in the circuit as drawn, the choke is simply in series with the transformer secondary, so you must reverse the current in it between half-cycles to get conduction on both half-cycles. It will not behave anything even close to the way that a full-wave rectifier feeding a choke input filter will.

Suggest you try a simple Spice (e.g. the free LTSpice from the Linear Techonolgy website) simulation of this and the normal full-wave circuit, and look at the huge differences. Note especially what happens when you vary the DC load on the output.

Cheers,
Tom

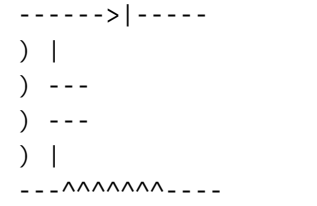
Why you all may be right, what you are failing to see is that
the choke is simply in the negative leg of the positive half
wave rectifier, and in the positive leg of the negative half
wave rectifier, and both rectifier outputs are in series.



This is a half wave rectifier with a choke input filter with the
choke in the negative end. Will this work? Now connect
this circuit in series with negative output half wave and you
notice you have two chokes in parallel. Yes you do need a
bleeder resistor or minimal load to satisify the choke current
requirement, I simply didn't draw this, the resting current
of a class AB1 linear would satisfy that.

Now what am I failing to see?

Ken-

This doesn't make sense to me. My recollection of the choke-input filter,
is that it can only be used following a full-wave rectifier. You are
suggesting they be used prior to the rectifier, which is not where a
"filter" is normally placed. Instead, the choke would act as a series
impedance to the AC source.

It seems to me that you can't separate the capacitors from the rectifiers,
or you wouldn't have doubler action. Therefore, capacitor-input is the
only filtering that makes sense for this circuit. Of course you might use
the choke in a Pi configuration between the output and another filter
capacitor.

If you have any success with this approach, it will be from extra voltage
generated by the choke's collapsing magnetic field. This is similar to
how switching regulators work, but without any active regulation.

Not at all well, because you have provided no path for the inductor
current when the voltage from the transformer tires to reverse bias
the diode. So the inductor will keep the diode conducting as the

voltage reverses. This is not at all the way a choke input filter
acts with a full wave rectifier. I am quite sure you have never seen
a choke input filter in a half wave supply, for this reason.

> Now connect

That there is a second current path through the inductor that involves
the other rectifier. So AC is applied to the inductor, instead of
unidirectional voltage.

And so, on and on go the anti CB and anti-M3 ramblings (rumblings?)... What about volunteering to serve on the RSGB or is that too hard? Just better to crticise... And what about showing new M3s a better way to behave.. by **example**. Nah, just gripe and snipe.. easier.

Polymath wrote:

etc. etc. etc.

Most (not just CB and M3) amateurs, sadly, use off the shelf cheque book purchased rigs and accessories. Amateur radio *has* changed. I think it was better BTW, but that has been changed by technology. The number of intolerant people blaming the wrong things has not changed - just become more readily readable by eg newsgroups. Again, simply the march of technology. A good hobby would move with technology. Adapt where it has to, and always be positive. Most of you regulars to this NG do not adapt. You are negative and destructive (eg towards the RSGB and M3s). Your continual sniping about both is a bore. References to eg Potty Bar were once mildly amusing but now tedious. Specifically, someone on here recently reported that he had been wrongly castigated by an M3 for transmitting off channel. A clear case of where technical experience was lacking. An amateur with the true spirit would have tactfullly explained the facts. And that was one of the *better* comments! Most are non-specific and generalised sniping. Yes, there are poor M3s, and there are also poor full calls, and poor but fast CW senders and so on. Any non-amateur who lurks across this group will quickly form an opinion that radio amateurs are a bunch of negative misfits and the sooner that BPL for the masses reduces their facility the better. BTW, for reasons beyond my control I'm not a member of the RSGB. I'm not an M3 either. Just an amateur. And why do I bother, I sense some ask. I suppose I'm still an incurable optimist who thinks some conscience may be pricked and this behaviour improved.. Why be here at all (Jock - one of the

better ones - asked) See my earlier reply. Come on chaps and chapesses. Lift your game. Time is running out. Do not be like the famous Australian amateur (a UNIX expert) who responded to accidental OT posts to their newsgroup (I think it was then called just "radio") in the early days of the Net by flaming. His "cleverest" flame was metres long printouts which informed people they were on the wrong group. By giving such a negative image to amateur radio to so many technically curious people (surely exactly those we want) he did a great deal of lasting damage to the amateur cause - perhaps aided in its disappearance. He is actually a public-spirited amateur, but what an error! Some of you are public spirited too. So for those, a plea for more tolerance. More thinking before putting keyboard, mouth, key into gear... Or will the replies show the absolute opposite? We shall see.. Time gets short. BPL for HF and other pressures for VHF/UHF/SHF could arguably squeeze us all out. The efforts of this group do not help in resisting this. They vastly aid it. Any lurkers are going to have a most negative impression of what probably are a bunch of fine people doing their best to hide it! "Amateur radio - so that's what it's like - best legislate against it without delay!" Anyone got anything *new* to add? Usenet is meant to aid debate, so have a go. But please not the usual, broing, repetive stuff; we've read it all before... Thanks for reading this; I now feel slightly better...

I played around with choke input filtering for this circuit with Spice
and got "continuous inductor current" if I used two highly coupled
inductors, one after each rectifier, and another pair of diodes from
the input side of the chokes to the capacitor common point. However,
this "continuous current" switches back and forth between the two
coupled inductors on alternating half cycles so each end of the
capacitor pair sees current as a half cycle approximately square wave
pulse. So each capacitor charges and discharges with a quite

triangular voltage ripple. But the sum of the two capacitor voltages is a very pure DC, compared to the no choke version, since the ripples cancel quite well. However, this reduces the output voltage to only half of the no choke version, so you might as well have made a full wave supply, instead of a doubler configuration.

5265. Re: Trickle Charge Battery

Although most posts have suggested what you are thinking of is a deep cycle marine battery or similar, you might consider using an SLA for your purpose.

SLAs will probably be more expensive, per amp-hour, than a marine battery. However, most lead acid batteries are intended to be operated outdoors. SLAs are a lot more housebroken.

With an ordinary lead-acid battery, you have two problems. The obvious one is leaking acid, which could be a real problem in the house. The other is outgassing hydrogen. Hydrogen is extremely easy to ignite, and if the concentration gets within the flammable range, it will almost certainly find an ignition source. Outdoors it is pretty tough (relatively) to get the concentration high enough to burn, but not so indoors. Hydrogen burns very quickly, so the result of a hydrogen fire, even in an open space, is often much like an explosion. The good news is that is has relatively little energy, so while it burns very hot, it tends to be over with very quickly, so it is (relatively) unlikely to ignite things around it. Still, I'm not the biggest fan of indoor explosions .. at least in my house.

With SLAs, neither the hydrogen nor the acid gets out, so they are a little more friendly indoors.

I guess I can't recall seeing a half wave rectifier circuit using
a choke input filter, but I thought that was because half wave
circuits are usually used in low voltage circuits where a choke
input filter would not have any advantage anyway.

However in a full wave circuit how is there an alternate path?
The center tapped transformer simply provides two ac excitations
to two rectifiers 180 degress out of phase. This allows only
one rectifier to conduct at a time. True, there is a more or less
constant excitation to the choke, but there is NO reverse path as
the diodes still only allow conduction in one direction.
Either way the choke sees a DC current, not an AC one (minus the
ripple, which a half sinewave imposed on a dc current).

I think I understand what you are saying here, but even with
a full wave rectifier doesn't the current through the choke drop
to zero (though only for a brief instant) between the two phases
of rectification when the diodes switch roles? And since there
isn't a capacitor before the chokes the voltage at the input
to the filter would drop to zero, unlike with a capacitor input
filter.

Also, with either type of rectifier (FW or HW) is shouldn't matter
which leg the choke is placed in, as Kirkoff's law is satified
either way.

The advantages of a choke input filter (lower RMS transformer current per amp of DC output, much lower high frequencies in the ripple, less voltage sag with increase in load current, etc.) are not directly related to the output voltage. The concept of a choke input filter is that the current is continuous through the inductor, and so, into the capacitor. A capacitor input filter charges the cap during brief pulses at the line peaks, instead, producing a higher RMS transformer current and higher harmonic ripple components, but also higher peak output voltage.

> However in a full wave circuit how is there an alternate path?
> The center tapped transformer simply provides two ac excitations
> to two rectifiers 180 degress out of phase.

The inductor current switches from one rectifier to the other as the transformer voltage goes through zero. At the moment the transformer voltage is zero, the inductor draws current through both rectifiers, producing an input voltage to the inductor 1 diode plus transformer resistance drop below the center tap voltage.

> This allows only
> one rectifier to conduct at a time. True, there is a more or less
> constant excitation to the choke, but there is NO reverse path as
> the diodes still only allow conduction in one direction.

I suggest you follow those currents through the inductor for a full cycle. Since the inductor is in series with the secondary, if the secondary conducts in both directions (alternating which diode is conducting) then the inductor must also conduct in both directions.

> Either way the choke sees a DC current, not an AC one (minus the
> ripple, which a half sinewave imposed on a dc current).

The diodes are turned opposite ways, so one conducts DC one way, and one conducts DC the other way. Both those currents pass alternately through the same inductor.

5271. Cleaning Tektronix TM500 series cam switches??

Hi folks.

Wondering if anyone here knows a good way to clean and restore
life to the rotary cam finger switches like are used in Tek SC502,
SG503 etc.

I don't have any of the blue and the red CAIG fluid anymore but
to anyone here who ever used it what do you think of the stuff??
I had two little bottles with a built it applicator brush and I
thought the stuff worked great!

My SG503 went bonkers and I used spray isopropyl alcohol and then
a small shot of WD-40 on the contacts. Seems o.k. now.

Some Tek components come with a warning not to use anything stronger
or more persistent than high-grade isopropanol on their switches (e.g.
the attenuator switches in the 4xx-series o-scopes). These switches
incorporate materials which can be damaged by many organic solvents,
or are used in high-impedance circuits in which small amounts of
leakage current from contact-cleaner residue can mess up the behavior
of the circuit.

> I don't have any of the blue and the red CAIG fluid anymore but

> I had two little bottles with a built it applicator brush and I
>thought the stuff worked great!

Agreed.

Both the original (German) Cramolin products, and the DeOxIt
formulations which Caig is selling these days, seem to work quite well
for many of these sorts of problems.

> My SG503 went bonkers and I used spray isopropyl alcohol and then
>a small shot of WD-40 on the contacts. Seems o.k. now.

Ugh. I would never recommend using WD-40 on electrical contacts in
fine electronic equipment. It gets gummy with time, and attracts
dust. It may make things better in the short run but I fear that if
it's left in place it may cause further (worse) problems.

I'd recommend flushing it out with another spray of isopropanol. If
the switches do need lubing, check the Tek manuals for the proper
procedure, if you can. Some of the modern contact-and-control
lubricants are designed both for electrical stability, and to stay
where they're put and not migrate around where they aren't wanted.

Bill,

Put me on your list as well, as I have a GX3000 as well. I also have the
Standard software but haven't figure out what they are doing to
with in the program either. Also don't have a spare eprom to work with
either.

5276. Re: choke input voltage doubler?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-20 06:28:28 UTC
From: K7ITM <k7itm@msn.com>
Message-ID: <1132468108.016464.141440@z14g2000cwz.googlegroups.com>
Source record: 16159

No, with sufficient load current, the choke current never goes to zero. See the formula for the minimum choke inductance versus supply voltage and current...the usual formula also assumes 60Hz--->120Hz ripple. Remember: V=L*di/dt. The output DC voltage is the average of the input voltage to the choke, less any I*R drop in the choke. It MUST be, or the current in the choke would change until it was. So the output voltage is (nominally) 0.9* the RMS input voltage, or 0.9/sqrt(2) times the peak voltage, assuming the choke input voltage tracks the full-wave rectified sine (in other words, the absolute value of the sine). When the input voltage to the choke is > the output voltage, the choke current increases. When it is less, the choke current decreases. The average choke current must be the average load current, or electrons would accumulate somewhere. If the inductance is large enough, and the cycles come fast enough, then the change in current is less than enough to make the current go to zero.

It's a bit of calculating to do it for a sine wave. Just think of this example: a square wave that sits at zero for one second, then at 2 volts for one second, then repeats. Feed it to a choke, say 2 henries. Output of the choke to a mongo capacitor, so the output voltage doesn't change significantly. Put a 1 amp load current on it. The output voltage must be one volt, since that's the average of the input. So half the time the choke has one volt across it in one direction, and half the time it has one volt in the other direction. One volt divided by two henries is half an amp per second. Since the average current is one amp, the current must swing between 0.75 amps and 1.25 amps. It never goes to zero, or even close. But drop the load current to 0.25 amps, and the choke current goes just to zero when the input is at the end of the low period. A bit lower load current, and the choke current would go negative (or to zero if there's a diode keeping it going one direction only). That's why a choke input filter looses its good regulation if the load current gets too small.

In the full wave rectifier, the choke current (if it doesn't drop to zero) will force the diode output voltage to be one diode drop below ground, PLUS the I*R drop in the transformer winding, when the voltage across the outside of the secondary is zero. At that point, both diodes will be conducting equally, assuming they are matched, and half the choke current will come from each half of the transformer secondary.

Hope that helps!

Cheers,
Tom

(off to Holden for a week...no internet there, so you're in John's capable hands on this one!)

Agreed - WD40 is good for de-gumming your chainsaw, preventing rust on garden tools, and freeing up rusted bolts, but thats about it. BP grade isopropyl(sp) alcohol is readily available from chemical suppliers - (A litre bottle will last you for EVER) - if you do insist on a "tougher: lubricant, then CRC 2-26 is pretty good. BUT - as in everything else - RTFM before you do ANYTHING!

"TFM" for WD-40 is at:
http://www.wd40.com/Brands/wd40.cfm

The website enthuses about all the uses of WD-40, including that it
"dries out" electrical systems. (Recall that the "WD" stands for "water
displacement".)

But even on their own site, I couldn't find any word about WD-40 as a
switch cleaner and contact lubricant... and that speaks loudest of all.

However,

[ ] In the UK, no repeat no licence of any kind is necessary to specify, design, construct, modify, repair, own, or (under some circumstances) test an Amateur transmitter.

[ ] A pass in a current examination for a UK Amateur Licence qualifies the successful candidate for the issue of a UK Licence. Holders of the appropriate levels of licence are permitted to operate transmitting equipment that is not subject to a formal approvals procedure, and to carry out technical investigations. A qualification for a Licence, or the Licence itself, is not, repeat not, a qualification to specify, design, construct, modify, repair, or own transmitting equipment.

> either way.

Spamless-

Yes, it wouldn't matter what leg the choke is in as long as it is on the
output side of the rectifier (assuming full wave).

For Half Wave, you must also consider the voltage across the choke.
Voltage is L times di/dt where di/dt is very high at the moment the diode
stops conducting. This is why a diode is often placed across a solenoid
or relay coil, to prevent a high voltage pulse across the switching
device. As a side-effect, relay drop-out is slow since current continues
flowing as the magnetic field is discharged.

With the relay analogy in mind, perhaps there could be some advantage if a
diode were placed across the choke of a choke input filter fed with a half
wave rectifier. It would be connected with cathode towards the cathode
end of the rectifier, and would allow choke current to continue flowing
during the off-portion of the rectifier's conduction cycle.

> not the one I want!

Ron-

If you plan to use the existing power supply, then the rectifier is most likely capable of handling as much current as the the transformer can deliver. If you don't want to trust it, one ampere silicon rectifier diodes are relatively inexpensive. Choose a set with reverse voltage greater than three times the transformer's RMS voltage (2.83 plus safety factor).

I believe the OA2 is a 150 Volt gas voltage regulator tube. That would provide stability for the plate supply of your oscillator stage, or at least its screen voltage supply.

The 6AL5 may be a dual-diode used as a meter rectifier. I'm not familiar with the others, but you should be able to obtain their rated filament currents to size the transformer's filament winding.

5294. SLA charging question.

Newsgroup: rec.radio.amateur.homebrew

Source record: 16177

Hey guys... I've spent lots of time looking over google archives for the answer to this, and God knows this has been covered many times, but I've not quite found my answer.

I have the following QRP power supply/charger http://www.mfjenterprises.com/products.php?prodid=MFJ-4114 .
Basically it comes standard to charge a 12 nicads, but I took out the nicad holders and put in a 12v 5AH gel cell. I modified it to charge directly from the 13.8v power supply instead of the 18v nicad charger circuit. I charged the battery to about 13.8v (w/ no load) by floating. If I measure the battery while having my radio on receive, which only draws maybe 80mA's or so, I see the battery dropping by .10's of a V in no time. The battery is brand new.
I've noticed that the battery only draws about 30mA's while charging at any voltage. I even added a switch so I can switch extra diodes between the regulator ground so I can charge it at 14.X volts.

So my question... If it measures 13.8-14v after charging, it should be fully charged, right? Is there something going on since it is only drawing 10's of milliamps while charging? I've read that they charge at several hundred milli's. I'd like to use my QRP rig remotely, and at the rate its dropping, I just don't think it will serve the purpose.

Thanks for all the help.

Jim, AB9LM

It takes more voltage to charge a battery than what it is rated at. That is
the reason for an 18 volt charger voltage instead of 14 volts.

Just float charging at 13v8 isn't going to do a great lot for an SLA. Download
and read the following two docs from TI/Unitrode which will give you a fair
insight into the proper care and feeding of SLA's.

http://focus.ti.com/lit/an/slua115/slua115.pdf

http://focus.ti.com/lit/ds/symlink/uc3906.pdf

There's a lot of overlap, but good info, and that chip makes a fairly simple yet
elegant charger.

Me again.
Thanks for the info. I just decided to run it down to see how long it would go. Like I said before, after fresh charge, and the battery showing 14v, after aplying the slightest load, the voltage started dropping... it dropped down to 12.6 in no time, but.... its been staying there. I've had the radio on for a couple hours, and its not moved from 12.6v. I even keyed a bunch, and that draws about an amp. Seems its holding steady at that voltage under load.

Thanks again guys, your always more than helpful.

I was going to suggest that you do this. If you have the patience keep it up until the battery voltage really starts doing a nosedive. Radio Shack sells (or used to sell) a DVM with a serial output and a little scope program that was nice for collecting this sort of data.

"Rechargeable Batteries Application Handbook" by the "Technical Marketing Staff at Gates Energy Products" indicates that a SLA battery isn't really discharged until it's down around 1.8V per cell. I'm not sure that I'd take it that low, but 12.6 - 12.8 is what you expect from a six-cell lead-acid battery that's not being charged, and it will hold that voltage for 70-80% of the time that it's discharging.

It's a good book, by the way. It's no more technical than the ARRL Handbook, and it has slews of information about NiCd and lead-acid batteries. It's a bit light (and a bit out of date) on NiMh batteries and it came out before Lithium Polymer batteries were on the market, but other than that it's a fine resource.

Here is a fixer-upper HP-23A on eBay Item number: 5831350002

You can even use the HP-23R replacement board
http://www.theheathkitshop.com/hp23r.html

IF you do not desire to change out the existing capacitors.

I am the "lucky" owner of a number of older UPSes.

So what can a person build out of these?

The batteries are for the most part dead but the remainder of the components seem to be in good condition.

Any suggestions?

Thanks

If you can get your hands on a copy of the 2005 ARRL Handbook, there are several suggestions in there (radio-related, but you can improvise from them), and some information about UPS's.

One is a charger for 12V storage batteries in general, including car batteries. Another is an emergency power supply (you can just run two wires to your car battery, or a bank of deep-discharge batteries wired in parallel if you're so inclined). Depending on the model you have, you can get 160 W to over 300 W of 120 VAC and/or 12VDC from them.

Mine (an APC Back-UPS 600) is now wired to an old car battery. It will run my computer for a lot longer than the old gel-cell that came with it. Since we're on the end of a power transmission line, it gets a fair amount of use.

A local college student has a successful business placing new batteries in
these units -- checking out and selling on eBay and to a large number of
local small companies.

I usually pickup the transformers from his junked units (fire, internal
damage).
This are usually good for 13.8 VDC linear power supplies in the 7 to 25 amp
range.

Yep, the power transformers in them - feed the local mains voltage BACK into it, you will get 18v (usually centre tapped) on the other side where the original switching transistors were, nice big thick wire - good for a few amps. As well, lots of other windings, good for what have you voltages.

I have a back-UPS 400 with a useless gelcell. However, touching
terminals of a fully charged and healthy gelcell to the battery
leads causes mega amps to flow, so something is likely fried.
Interestingly, the dead battery has about 10.5 volts on it,
in-circuit, no current!

Anyone got a schematic or wisdom to share? / thanks / mark

Do you have to worry about fumes from the car battery, or do you only use
the "sealed" type of car battery?

I replace the batteries. I get them at the MIT flea market, two for 10
bucks. Yes, and they have a test load there so you can verify the
batteries are good. I have had not problem.

I have several free UPSs because clueless people have thrown them out at
our recycling center as they are "bad."

Al

Generally you can get new batteries from a local battery distributor at very good prices and with local pickup no shipping costs. I used to use Midstate Battery in Bloomfield, CT but there will be wholesale distributors everywhere. With new batteries most UPSs will be good as new.

Keep what you can use and sell the rest locally, donate a few to the local senior center for a tax write off (yes seniors use computers these days), etc.

This is the classic symptom of a 12-volt lead-acid battery with one cell shorted. Hooking a 12-volt battery to a 10-volt battery will draw lots of current, as observed. Replace the old gelcell battery with the new one; do not keep the old gelcell in the circuit.

These SLA =Sealed Lead Acid batteries usually have a charging rate for 2 types of usage The YUASA battery I have in front of me has the following instructions (applicable at 20 degrees Celcius) :
Standby Use : Voltage regulation 13.50 -13.80 V Initial current : No Limit
Cyclic Use : voltage regulation 14.4 - 15.00 V Initial current: 1.75 Amperes max.

I also use a number of SLAs without such instructions , which I (safely) charge at 0.1 C (for example a 7Ah battery is charged at 700 mA) and limiting the Voltage to 13.5 V ,bearing in mind that 12 V lead acid batteries are still 70 -80 % charged when voltage has dropped to 12.6 V
To test (charged)12 V lead acid batteries I discharge them at a constant 0.1C current and check the time until the voltage has dropped to 11.9 V (at that voltage the battery might not as yet be fully discharged ,but below that voltage they are of no use to me)

==========
The 'fumes ' you refer to are hydrogen and oxygen ,with hydrogen potentially dangerous when not vented.
That's why I keep non-sealed lead acid batteries on a well ventilated loft.

BTW : Hydrogen has such a low density that , as tests (not by me) have proved , it is impossible to ignite hydrogen released from vertically positioned tubing by a naked flame located at a distance of more than 100 mm (4 inches) from the hydrogen exhaust.

Providing this info does not mean I wish to encourage anyone to 'mess about with hydrogen'.
It is only to show that hydrogen doesn't spread throughout an enclosed space but ,upon release, moves upwards very rapidly .

Looks like you have some good info from others. Here's a little more.

What you will be doing is not "trickle" charging, but it is called "float" charging. Lead acid chemistry, similar to Li-ion (unlike ni-Cd & Ni-Mh) has the characteristic that it has a voltage charactistic such that the terminal voltage rises between dead and full charge. You can safely put a constant voltage (but also with a current limit) on the battery and it will seek its own full charge and the current will taper off, when it gets enough, to what it needs to stay at full charge. CAUTION -- This voltage is typically around 13.8, HOWEVER you MUST consult the manufacturer's specs. This voltage also changes slightly as the temperature of the battery changes.

A commercial device designed for this service is recommended.

Um, I didn't make myself clear, I guess - I took the old one out,
clipped to the new one, instant heat. Big heat.
I'm guessing that there's circuitry which avoids draining the
(bad) low voltage one past a certain point. I'm also guessing
that a fully charged battery (the one I tried to hook up) enables
current flow, and that perhaps the input of the invertor section
is shorted. I didn't feel like leaving a perfectly good 17A-hour
battery to fry itself and the surrounding wires etc.....

BUt thanks for the response / mark

Some real brain fodder here. John P. Your Spice model with the coupled inductors seems to take a divergent turn and I am not sure about this "coupled" part. Did you try a single inductor.

On to my original thoughts. This really takes me back and requires serious thought. One thing to keep in mind. An inductor (by virtue of the magnetic field cutting its own turns) tries to keep whatever current is flowing, flowing. An inductor will make the voltage across it "do whatever it takes" to keep that current flowing-- and allow this current to decay (some say discharge) in what can be considered a normal manner. The diode on the relay coil is a good example. The voltage can rise very high without the diode, but using this model, you can figure out what the inductor voltage does when the normally conducting device turns off.

That said... I had never studied choke input filters to such a degree... However, its action must allow the filter cap to charge for a longer time, thus keeping the average diode current lower...
Does the current through the inductor drop to zero in the normal choke input filter?
If not, a close look at the current path in the full-wave circuit will show where the current goes at the cross-over points. Brain full - can't figure out now. I'd have to model it in Spice and watch things

Very interesting thingh. If the current does drop to zero, then it seems the single choke would work.

Then, reading some of the latter posts, I too, wonder why the desire for choke input.

Not sure who the OP is here...

I gave some relevant info in another thread (Below), but here's some additional info.

The lead acid chemistry's voltage goes from just under 12 volts at dead, to just over 12 V at full charge (Don't remember the exact, but the idea holds). HOWEVER, this is ONLY after "RESTING" for some time. I never found out (or perhaps remembered) what this resting time is, but think it is perhaps half to one hour.

Float voltage is around 13.8 (I have some Yuasa SLAs and they say give a range of around 13.7-13.9 for float). At the float voltage, they will "take what they need" to stay charged, but that is NOT the terminal voltage after resting, or when delivering current. This is what I say above.

In addition to the constant voltage float, you MUST also limit the current to some maximum (specified my the mfr) when a dead battery is first put on the charger. With a high current 13.8 supply, you can damage (explode, or whatever) the battery with too much current at this time. Once the battery gets up to the 13.8 float voltage, the current will begin to drop and the constant current part of the charger will fall out of use and you have a constant voltage, where the battery top itself off thing going on.

Steve

> . . .

In a properly designed choke input filter, the choke current never drops to zero. If it does, the circuit becomes the equivalent of a capacitor input filter, with the capacitor furnishing the load current and the voltage increasing as the whole thing acts more like a peak detector rather than an averager. This means that a common choke input filter requires a minimum load current if it's to always behave like a choke input filter.

Quite a few switching supply topologies also include an inductor. In the ones I've designed, diodes are used to provide a path for inductor current between input pulses. Diode reverse recovery time becomes important as the switching frequency increases, since it dictates how quickly the diode can turn off once the voltage across it reverses. It's often possible to design a regulator which will tolerate the inductor current going to zero. But it requires special care because the relationship between input pulse width and output voltage becomes very different(*) and it can be tricky to make the regulation control loop operate stably and correctly under the two very different conditions.

(*) While inductor current is present it behaves like a choke input filter, the output voltage being essentially the average of the pulsed input voltage and so easily controlled via the duty cycle of the input. If the inductor runs dry, the output voltage becomes relatively independent of the input duty cycle -- it becomes the peak value of the input during the input peaks, and sagging between peaks according to how much current is being drawn from the capacitor.

Steve Nosko wrote:
> Some real brain fodder here. John P. Your Spice model with the coupled
> inductors seems to take a divergent turn and I am not sure about this
> "coupled" part. Did you try a single inductor.

Yes. First I tried a single inductor in the common leg of the
transformer. I used a 1 Hy inductor and two 220 uF capacitors and a
100 ohm load resistor across the doubler, with a +-10 volt peak sine
source as a transformer secondary. The inductor current settled to a
+24 mA to -24 mA sine wave. The output voltage across the load
resistor was about .825 volts with a 120 Hz ripple that swung from
about .77 to .88 volts. Not much of a doubler. Almost all the
secondary voltage is dropped across the inductor.

I also tried several different configurations with two separate
inductors, one between each diode and capacitor. Only the coupled
inductor did anything like a choke input filter. And such coupled
chokes exist. See type 2-2690 and 2-2691:
http://www.stancor.com/pdfs/pg56.pdf

The relation between voltage and current is V=L*(dI/dt). The only way
the current can change is if the inductor has voltage across it.

> on the relay coil is a good example. The voltage can rise very high without
> the diode, but using this model, you can figure out what the inductor
> voltage does when the normally conducting device turns off.

Yes. The current ramps down as determined by the drop across the
inductance. In this case, that is a diode drop added to the resistive
drop of the coil.

> That said... I had never studied choke input filters to such a degree...
> However, its action must allow the filter cap to charge for a longer time,
> thus keeping the average diode current lower...

Make that "the peak diode current lower". The average diode current
has to be equal to the average DC output current, regardless of the
filter.

> Does the current through the inductor drop to zero in the normal choke input
> filter?

If the inductance is below the critical value, it certainly does. But most choke input filters are designed to produce continuous (but varying current) throughout the cycle at minimum current load. But all choke input filters will go into interrupted current operation at some minimum load current.

> If not, a close look at the current path in the full-wave circuit will show
> where the current goes at the cross-over points. Brain full - can't figure
> out now. I'd have to model it in Spice and watch things
>
> Very interesting thingh. If the current does drop to zero, then it seems
> the single choke would work.

I guess that depends on what you mean by "works". It cannot ever work as a normal (continuous current) choke input filter.

> Then, reading some of the latter posts, I too, wonder why the desire for
> choke input.

It has advantages for lower transformer heating and low line harmonic currents and improved DC voltage regulation (compared to a capacitor input filter) with changing load currents (as long as the minimum is above that which maintains continuous current) and low output line harmonics above the second. If any or all of those are important to you, it may justify the high weight and cost of an inductor.

5327. "Standard parts" for rf amps?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-22 00:13:42 UTC
From: Henry Kiefer <otc_friend@gmx.net>
Message-ID: <438262c8$0$27904$9b4e6d93@newsread4.arcor-online.net>

Hi all -

I'm not new to electronics but to vhf comm. I want to build small circuits:
LNA, power amp to 10 watts, etc. At the moment between 10MegHz and 150MegHz.

What are the standard parts, cheap but effective, preferable with spice
model availability (I'm doing much with LTspice)?
Transistors, ICs, coil-suppliers, suppliers in general for small quantities

Please no triodes etc. I like more SMD ;-)
Lists somewhere in the net? Japanese parts?

I think such lists will be of interest to others too!

Thank you!!

Best regards -
Henry

Would a 12 V deep cycle- Optima work in a APC-UPS 1400R I keep my servers and dyno on with it along with some routers and switches. I don't know the output, the battery fails and I now have it frightfully bypassed. The batteries died and are almost 2 bills to replace. voltages ? issues? but I have a few Optima batteries from wrecked race cars that would be perfect!

Any input would be appreciated,
Rob

Yes Jim!
Im not very experienced there (Digital designs/layout is my profession) -
but for example I designed a LNA and got simulations results (even for noise
performance) very similar to a real circuit built from a ham with great
background (found later on the net).
Even a Synchronous Oscillator for 145MegHz seem to work with LTspice. I work
on it today trying to modify it to an fsk modulated power oscillator to keep
component count to the lowest.

Why you ask?

No list needed!

VHF traditionally begins at around 6 meters, but design techniques there are not much different from those used at 10 meters. The point where you need to begin being more careful regarding circuit layout is around 2 meters. Many devices that operate on the lower shortwave bands still function reasonably well at this region. So... the same analog circuits will work, but WATCH OUT for circuit layout.

Double check the Powerwerx site, as I seem to remember them having
larger than 75, maybe only 150. Just checked. See:
<http://www.powerwerx.com/category.asp?CtgID=3579> where they have up
to 350 Amp ones. If that's

At some hamfests, there are dealers who have used ones from electric
forklifts and other industrial equipment. Good prices, although you
may not be able to reuse the contacts. Contacts for that size will
require a major league crimper (pneumatic or hydraulic). More
practical would be a large soldering iron.

As an aside, when you get to the larger wire sizes like 1/0 or 2/0
(pronounced one aught or two aught) you would want welding cable.
Welding cable has the same cross sectional area of copper as regular
wire, but has a larger number of finer strands, which allows the whole
thing to bend. Regular wire in that size often needs a large tubing or
conduit bender to shape it.

If you need more than 350 Amp carrying capacity. . .
Happy trails,

Unlikely, but while the replacement batteries may be, as you say 2
bills, from APC, if you take the old ones to a proper wholesale battery
distributor they will in all probability be able to sell you proper
replacements for about $20-$25 ea.

If they are 'Red Top' starting batteries, not really. Starting duty
batteries aren't meant to be deep discharged, even if the Optima
starved electrolyte design will take the abuse far better than most
because electrolyte volume is restricted.

If they're the Yellow Top deep-cycle, or the Blue Top Marine
starting/deep cycle, and the voltages are right, yes.

But realize it might work TOO well when compared with a standard
gel-cell battery. Those Optima batteries can deliver frightening
amounts of short-circuit current for several seconds and the circuit
can fry before a fuse can react.

Sure! I have a few of them. I usually get them for free because they are "broken". I replace the batteries and they are as good as new. I have even gotten a hold of an expensive "sine wave" UPS. Most UPSs use a sum of square waves to simulate the 60Hz sine wave. There are lots of transients and noise, however. Some (expensive) UPSs use a different type of inverter and produce pure sine wave AC. If you put an accessory plug in the side, you can use it to keep the batteries topped off and plug into the accessory plug for volts. Be careful though, the better ones use 2 12V batteries in series.

Russ

You need to be very careful with this - I have seen units that have one side of line voltage on the battery terminals. This is not a problem with the batteries sealed in the UPS, but could be a big problem if you try to bring leads out to charge a battery.

I have about 25 UPS' I picked up at a local university sale for $30 total. The largest was a 2KW unit with 18 12V batteries, one of which was dead :-). Metalworking content - after replacing the one bad battery I tested it using my bandsaw....

Ok Jim. You're asked about the stray components hidden in the real parts/circuit. If you take the values from the datasheets for die and/or package or give it a guess if not available, and add values for the pcb lines, you have a good simulation result. The pcb by itself is not of much interest if you simulate not much over 100MegHz. Even starting a oscillator with thermal noise is possible!
Sure, you must know what you're doing :-)

Spice by itself can simulate almost all if you have the right models included - even if you wanna simulate a mechanical system. There is no frequency limit at least to 100GHz.

Do you had bad result doing Spice?

To come back to your question: Spice will give you better results than your real circuit! You can connect a probe with no interaction to the circuit! Try this with your real parts! Don't forget the component variations in real circuits coming from the manufacturing processes of the parts.

- Henry

==========
Suggest you check the charging instructions on the original battery and
compare these with the ones applicable to the Optima type of battery.
The battery in a UPS is on 'standby duty' The charging instruction for a
YUASA SLA found in many UPSes has the following for standby duty :
Voltage regulation : 13.5 - 13.8 V
Initial current : Unlimited

Connect the Optima battery to the UPS and check the voltage when the
battery is fully charged . You can charge the battery externally to say 13.5
volt before you connect it to the UPS. If the fully charged voltage is in
the above range ,you can safely use it for this purpose.
I would think that any 12 V SLA will happily work with your APC UPS 1400R
,provided its capacity is adequate for the load to be maintained for the
minimum time needed. If you use a number of batts in parallel ,please
ensure there is an adequate FUSE in each battery circuit !
You can also connect a much larger 12 V sealed battery to the UPS (for
example those used in electric golf trolleys). Even non-sealed batts can be
used provided they are located in a well ventilated area .
I have non-sealed batts located on the loft connected via leads made from
welding cable running to equipment in the ground floor radio shack (to feed
radio equipment requiring a peak current not exceeding 25 Amperes)

Above I mentioned batts for Golf trolleys because their cost is very
reasonable nowadays there being a relatively large demand , hence
competition (pun intended)

Bob , Interesting info ; can you confirm that the 18 pcs 12V battery were
in fact 9 strings of 2 batts in series (each string having a fuse)
providing 24 V ? or were all the 18 batts in parallel ?

Minicircuits the MIMICs and mixers are of most interest and there
are inexpensive versions in the line up. What both offer is well
characterized RF 50 ohm port parts that behave well in circuits.
For example you can build a DBM, can you say for sure what the
characteristics will be from say 2-500mhz?

Other useful parts from there are VCOs and RF transformers.

If the inductor in your design is replaced by a piece of wire, the diodes will directly charge the two capacitors and the connected equipment will draw charge from the capacitor pair.

If you then replace the wire with an inductor, ALL that will change is that the capacitors will charge less effectively and you'll have a less efficient, bulkier and more expensive power supply.

As simple as that? ;-}

There is nothing hidden at all. Strays are a part of the real life at VHF
and above. Sometimes strays have more effect than the part itself.

Again I ask the question: What does Spice say about a 1000 pf capacitor
with 1" total lead length at 150 MHz.? Don't give me the BS about Spice
being "better than a real circuit". Until you can give me a ferrite slug on
one end of a toothpick and a brass slug on the other end to increase or
decrease inductance in Spice, the physical circuit is the "real" circuit.

Most likely six strings of 3, for a 36 volt system, or 3 strings of 6
for 72. a 2KW 110 volt system on 12 volts would draw close to 200
volts, on 24 close to 100, on 36 close to 60, and on 72 less tan 30
amps for 18 amps out and85% +/- efficiency.

This one interests me. Wonder how many small UPSs you could run from a truck battery (assuming using heavy enough cables between each UPS and each battery [when needed for the 24 volt input]). I am sure you would have to leave the vehicle running if running the UPSs for any length of time or heavy load... Probably pretty basic questions but I am kind of interested because I have a couple laying around and never thought of using them as an inverter (powered by a vehicle). That would make a neat addition to a garden tractor or something too...

There are 2 types of UPS. One, the load actually runs off the battery (the UPS just keeps the battery charged and inverts the DC power to AC) and the other the load actually runs on line voltage and switches to battery when line voltage disappears (this is probably the type you are speaking of but I have not tested that).
Also, should not need any heavier cables (except to account for the longer length that may occur between truck battery and UPS) as long as using the UPS within the design specifications. I think it is generally about 12 Ga. wire between the battery and UPS (at least in the PC world, servers might be a little bigger since the batteries are often in series).

Greetings.

A short while ago, I posted a request for links to simple triggered sweeps for older recurrent timebase oscilloscopes. I spent a fair amount of time looking in old magazines and circuit handbooks, but didn't find what I thought I was looking for.

So I decided to cobble-up a homebrew of my own. This circuit probably has been done before, but it met my criterion of being really simple. I used already on-hand parts, so the design is far from optimum. It works fine on an Eico 460 up to about 1MHz. No attempt was made to make a calibrated sweep. You could use a 5v rail and an HC4538 to make a nice high speed triggered sweep.

Have a look at:

http://novatech-instr.com/Fun/trig.pdf

Thank you to all of you who sent me emails and posted comments on these boards.

You have to put the strays into the spice model if you want an accurate
result, just like you would have to if you work it out with a pencil and
paper.

You can work out the inductance, resistance (including skin effect) and
capacitance of arbitrary structures using the free programs FastCap and
FastHenry, though these consider inductive and capacitive effects
separately so you have to break the problem into several parts sometimes,
e.g. if the structure is a significant fraction of a wavelength in size.
Constructing the model files can be tedious, and you may end up having to
write some code to automate it. You can view the model files using a
viewer program which used to be and hopefully still is available from
www.fastfieldsolvers.com You could also buy one of the commercial
full-wave solvers if you have more spare money than time.

Right but you have to do that one way or another anyway even if the model is
inside your head, unless you design purely by trial and error.

The real advantage of spice is in situations where trial and error is more
expensive than getting it right the first time (where you can justify
spending a long time making good models). He does also have a point about
being able to probe components inside a circuit that you could never probe
on a real one due to loading effects of the real probe. It seems to me
that your real objection is not with computer simulation of circuits, but
rather with poor models for components. Fair enough, garbage in garbage
out, but I would consider using bad models to be a form of 'user error'.

Chris

I think you could use an LM361 comparator in place of the front opamp.
It produces high going and low going digital outputs that you can
enable separately, so you can choose whether you want to sync on
positive going or negative going edges, without changing the switching
threshold.

It will also clock the flip flop a lot faster than an opamp will.

Assume the UPS was designed to properly charge the batteries.
Look up the battery manufacturer's recommended charge rate.
As a practical matter, that's probably the best most people
can do when the UPS specs are not available.

>
> Any test setup one can rig to measure rated charging capability?

Well, if you happen to have a high wattage fully adjustable load
(not very damn likely) and the wherewithal to fool the UPS into
"thinking" that a battery is connected (with a variable supply and
a diode or maybe a big 'lytic), you could plot a charge curve by
measuring the current through the load and the voltage across it.

>http://www.national.com/ds.cgi/LM/LM161.pdf

Yup, good call! I actually have a 361 based circuit I built a long time ago. It works to about 50MHz. It is overkill for this purpose, but would be the right choice, along with an HC4538, if someone wanted to modify this and go to higher frequencies. You actually have to move some pins around on the 4538 to make it non-retriggerable.

On the 361 board, I use long-tailed pair miller integrators to get near perfect sweeps. But that was a complete homebrew scope I designed in 1978 or so.

Thanks.

I tried a mental exercise, I redrew the voltage doubler adding another
winding to the power transformer to provide output 180 degress out of
phase and added two more diodes so I now had each capacitor feed by
both rectified phases. The result, is of course, a full wave bridge
rectifier, but with a center tap of the transformer coupled to the
junction of the two filter capacitors. This is similar to the
dual voltage power supplies so often seen in the ARRL handbooks from
the 60's and 70's for tube transmitters. I suppose a choke could
be placed in the lead from the anodes of one pair of diodes to ground,
so it would be commond to both outputs and the lead from the transformer
centertap isn't needed.

18 x 12v = 216v with plenty current...since you are with us I assume
everything went well? ;<)

Most are APCs but I have others (Best, Minuteman, etc.) and have access
to several others I have yet to see.

My questions are an attempt to learn so I can evaluate all them
properly.

I appreciate the information from those who have gone before and still
are around to tell about. ;<)

It would seem to me relatively easy to replace the horizontal sweep
oscillator with a 555 chip ! and trigger it with a sample of the
vertical Amp. signal !

If you have any Best Fortress 1420s of the older model with the 4 digit
display, I might be interested in purchasing them sans batteries to save
on shipping if the price it right.

Heck, that can happen before you hit 1MHz. Check out the ESL and ESR of a
47,000uF capacitor some time.

How about dielectric absorption ("soak")? I first encountered this in an electrolytic capacitor being used for generating a sweep of about a minute duration. The capacitor had to be kept shorted for several seconds between sweeps in order for the charge to adequately empty, an equivalent frequency of less than one Hz.

For some of the university work I've done, some of our reference papers are
from people modeling power lines as full-fledged transmission lines that are
many wavelengths long at 50Hz. No simple equivalent circuit model works for
them either!

I have two Minuteman units I rescued from work. Both just needed batteries.
I opened them up so I could get to the battery while they were plugged in
and checked the charging voltage. It was something over what the battery was
rated, 13 volts and a 12 volt battery, so I figured that the charging
circuit was ok. The UPS worked as far as running a load when unplugged, but
they had no reserve capacity so I took a chance and put batteries in them.

OK, I did get a little over-excited there -- it should say "that are
significant fractions of a wavelength long," (e.g., more than 1/6th) such that
you can't use a simple circuit model for them.

When they matter, just poke in the appropriate series L or a bit of
transmission line. I use Spice now and then to sim picosecond stuff.
Even if the simulation isn't highly accurate, it helps train your
instincts, shows you which parasitics will have which effects, so when
you build the real thing you have a jump on the complexity.

Hell, 150 MHz is slow.

Lumped L and C if things are slow, or a hunk of transmission line when
things get fast. Works fine.

That's interesting -- SPICE has models for (lossless) transmission lines, and lines of that length can also be adequately modeled with a few LC sections. I can imagine line loss could be tricky, though. I've modeled skin effect loss in the process of designing time-domain circuits to compensate for delay line loss over a wide time range (and therefore broad frequency range). But loss due to interaction of the fields with ground underneath the wires might be more difficult. At least you've only got one frequency to deal with -- unless harmonic content is high enough to worry about. Perhaps you've also got to deal with loss due to radiation?

Agreed, John, 150 MHz is damned near DC for a lot of us, but as yet I have no answer from the "spice" folks for the 1 nf capacitor question. A lot of fancydancing but no answers.

I am not an expert, but can you not just add a bit of series L to approximate this? Or even transmission line for higher frequencies / longer tracks.

I have had surprisingly good results simulating a single transistor UHF oscillator at ~500MHz. The results agreed with reality quite well, even *without* explicitly modelling all the parasitics. Certainly spice was better than me at predicting what would happen (although that is not saying much!) I guess perhaps the reason that I could get away with this was because of the small size and high performance of SMT parts these days.

Not very common on a unit as small as 2kW, but very common on units in
the double digit kw range. If he meant 20kW instead of 2kW, it almost
certainly had a high voltage battery string. Much more efficient to have
the higher voltage at much lower current to convert to the high voltage
AC. On a 20kW unit that would put your battery current in the 85A range
for a 2xxV battery string vs. 850A range for a 24V battery string.

Better check first if the UPS can handle a log term run of a battery. It
might be that it was designed for a short term, just to give you enough time
to power everything down properly. Longer runt time might cause some
marginal designs to overheat.

Pretty good. Did a similar thing using 3 555s. One was used as a
threshold detector, one for the Onshot (with a FET constant current
source) and one for the retrigger holdoff oneshot. Worked to well
to beyond the 5mhz scope it was used with.

Spice, smice. You got good answers. Wake up, spice is just an
engine to run your component models in circuits of your making.
Once one gets beyond the "toy" level of using spice it becomes
necessary to vet and complete the models of all your critical
components, including parasitic circuit elements. Want a good
RF capacitor model, you do well to make it yourself, from the
manufacturer's data and info, and from your understanding of the
part, aided by theory and bench measurements. Then vet your model
with more bench measurements. Thinking about component leads and
PCB wiring? Hey, you need to explicitly add all these into your
circuit. Just don't blame any resulting shortcomings on "spice."

I didn't realize that this question was addressed to all "'spice' folks", but was directed only to the OP. That's probably why the "'spice' folks" haven't leapt to respond. Anyone who uses SPICE professionally, and indeed a great number of amateur users should be able to answer the question easily.

At 150 MHz, a capacitor lead can generally be handled as a single lumped inductance. The amount depends on the wire's diameter and environment, but around 7 nH is a good working number for a half inch lead. The inductance of the capacitor body itself might have to be included in the model if high accuracy is important. Capacitance to ground, from both the leads and the capacitor body, might also be important if the impedance of the circuit to ground is high. If so, it can be included. The way I'd approach inclusion of the C would be to calculate the impedance and length of the transmission line comprised of the lead and ground plane or capacitor body and ground plane, then convert those values to a single series L and shunt C rather than just directly using a transmission line model -- very short transmission lines in a model can greatly slow SPICE calculations unless there are also other very short time constants involved.

On the other hand, if the "leads" are PC traces over a ground plane, shunt capacitance will be higher, and the approach I mentioned with the transmission line is the way I'd always do it. The model for the leads would include both L and C. As an example, if the "lead" is a .010" trace on .032" FR4 material (er ~ 5) over a ground plane, it makes a transmission line of Z0 = 105 ohms, velocity factor 0.55. The equivalent L and C of a half inch of this line are 8 nH and 0.73 pF respectively.

Other characteristics of the capacitor such as ESR might have to be included in the model depending on the application.

You gave a capacitor value in your question -- an ideal capacitor of that value would of course be the other part of the model.

SPICE is used daily, as it has been for decades, by professionals and produces strikingly good results in the hands of someone who is skilled at modeling and has a good understanding of the circuitry being modeled.

I've personally used SPICE for modeling linear to highly nonlinear circuits up to 50 GHz, where even tiny SMT components were often modeled as transmission lines and every pad and solder blob is significant and included. The results were used in the design of products which have been successfully produced by the thousands and sold for years.

The problem is the higher the frequency the more second and third
order effects are noted. A 1000pF cap at 1mhz is a cap for all
intents. At 150mhz it's now a complex RLC.

>On the other hand, if the "leads" are PC traces over a ground plane,

There is a point here where you have to ask is a PCB trace a cap,
inductor or more realisticly a transmission line. Each has it's model

and they are different. With two sided (or more layers) board the
transmission line model is likely the one to use. Especially if your
working with VHF transistors at any power level as impedences
are in the range of a few hundred ohms on the high side and fractions
of an ohm at the low side. Typical 30-100W devices have an imput
imedence under 2 ohms (and Xc) and output in the sub 4 ohms range
depending on power. In those cases everything counts and getting
hard numbers requires some work.

It hits a hard nail on what model to use and when because spice will
only give the results you asked for be they real or imagined.

>Other characteristics of the capacitor such as ESR might have to be
>included in the model depending on the application.

In most I'd naturally assume though at low VHF it's less signigicant
than at 2.4ghz.

>You gave a capacitor value in your question -- an ideal capacitor of
>that value would of course be the other part of the model.

And depending on frequency it may be a open ended transmission line
on the etch.

Spice is a great tool. Like every tool one must know how it works,
how to use it to its fullest and knowing the tool can hurt you if
abused. When introduced to spice for the first time I was told
garbage in, garbage out and never assume that computer
crunched garbage is anything other than composted garbage.
What I've found is that Spice does allow you the luxury of saying
"what if" or "how does that affect xxx" even if you are not sure it's
real.

No, quite possible and makes some design sense - they would not need
a heavy output transformer in the unit boosting the voltage of a 36V
or 48V battery string after converting it to a sine wave AC, as 216V
would be right around the sine wave peak voltage of 120VAC. Just run
the battery DC through two sets of power transistors to let through a
reconstituted sine wave - one for the positive half of the output
waveform, the other negative.

And it cuts the current the transistors have to pass.

hi very good point, many older units will not startup w/o
running from a/c power first.

Some newer APC models you can 'fool' it into
startup by pressing the test button with it offline.

Another factor, many of these older units like
the Exide, Best, Liebert and Trip Lite are
full sine wave units, a real bargian at today prices.

There was an article in QST on adapting a smaller
ups to run on an external battery. Very easy to to,
just use good fuses MaxiFuse on the leads.

Some of these newer units use microprocessors
to run the thing so if the don't power on without
batteries, they are useless except for the transformers.

Yes, very possible !
Exide models as well at the other big boys Liebert etc.
use this configuration.

They use torrid transformers, very compact,
the entire assy about the size of a loaf of white bread !

The ups w batteries about 36" cubed. 12 KVA 3 phased.

dude

I don't know why "RST" is so aggressive but I would mention here, that the
really funny part begins if you garbage in and get meaningful output!

I like to smell the solder iron but it can be very interesting playing with
Spice and see how changing values can and CAN BE NOT have a drastic result
in the simulation. Sometimes changes are not so great in result and parts
can be simpler made. e.g. changed from 1% to 5% or more.

OK Jim -

I simulated your question in a first trial. Here is the result:
approx. 70MegHz resonance for 100pF, 30mOhm ESR and 5nH for the trace.
Surely I would prefer smd chips having better results.

BTW: I cannot understand why you're so aggressive and I would prefer that
the thread will go in direction of my FIRST posting. I'm doing electronics
since I was 12 years old and that is 25 years back. I have for example a
patent application made and worked in the communication industry. So you can
surely think I know what I'm doing. Thanks!

You can that simulate as a rc coupled line of a few steps. That works even
for battery simulations.

Quite Plausible, but when you add the caveat of reproducing 3-Phase
power the engineering just got really complicated, and more than
likely rather expensive. And I'm NOT a high-powered electronics drive
wonk by any means, the best I could do for fixing them is look for the
obviously crispy components and swap out the blown boards - or swap
the crispy parts and diodes that fail a VOM test and see if that does
it.

With a single phase inverter, they're just doing a push-pull on one
240V lead, relative to the center tapped neutral. When you try
3-phase, there's going to be constant voltage, current and capacitance
interaction between all three sets of "hot AC" switching transistors
(or Triacs, or whatever). And the load's resistive, inductive and

capacitive components are all going to come into play.

The resulting inverter would need to be built rather robust, and be able to overcome drive issues with brute force where finesse won't do. Compared to that, RPC's are the KISS method. And RPC's aren't a bad way to go, if they are well balanced and have cooling air you can tuck them away in a closet.

Get your hands on a large, like 30kw or better, used as in "please take it out of here", three phase, online UPS from a computer room installation. As long as you can supply adequate power to the DC bus the inverter portion will happily generate your three phase power with no issues with designing and inverter or trying to synchronize three inverters or duty cycle problems. It's a DC - 3 phase AC continuous duty inverter, ready-to-go.

Such a question is stupid and incomplete. First of all, in
cases where impedance matters, one wouldn't dare use an inch
of lead at 150MHz, we'd cut that short, 0.1-inch max. And
we certainly wouldn't use an inch of pcb trace unless it was
field-controlled with a ground plane. This is true whether a
1nF cap is involved or not. If you were to insist on analyzing
an inch of lead, we'd insist on knowing *all* about the ground
scene. Since you aggressively put your question without any
relevant information about what the ground is like, and where
it is, the question is intrinsically-stupid and incomplete.

Sorry, jw\, but that's the way it is.

No way, I put in a 30kw 3 phase UPS (Best Unity/1) and it was close to a
ton with batteries. Without batteries (when I moved it across a raised
floor with a pallet jack) it was far under a ton.

>
> Since it needs a system for producing DC, it would be comparable to
> what the UPS already has.

It has a system for producing DC, it's just setup for three phase input.
Depending on how it is configured it could be quite easy to rework the

input section for single phase. The more modular the design the better and you might get lucky and find three discrete DC supplies, one fed from each phase, that couldn't care less if they were actually 120 degrees apart.

>
> That means that I would have a monster that weighs a ton.

That would mean you have all the clean sine wave three phase power your shop could need, uninterruptable no less, and heat for the winter.

>
> I almost bought a 15 kVa UPS though.
>
> i

The building I used to work in had about six monster UPSes in the basement, each feeding a 600A 208/120V 3 phase buss duct running up through the building to multiple PDUs. They had the nice 5 gal size glass cased batteries in the strings. Also had five 800KW diesel generators with paralleling switch gear and 40,000 gal of fuel supply. Redundant utility feeds as well. Place would have made a nice house if it was in a better location :)

And as I pointed out in the previous thread, that wave thirty years
ago of adding triggered sweep to older scopes did all use 555s for
the ramp generator.

I cleared off the scanner, and
http://www.cam.org/~blackm00/ramp.jpg
is the scan out of Howard Berlin's "The 555 Timer Applications Sourcebook
with Experiments" from 1976. The actual circuit was originally in Electronics
magazine for October 11, 1973, which I likely do have (at least

the part with the circuit) somewhere but can't be bothered looking.

And as I said, this basic circuit did seem to be the basis of
all those "add triggered sweep to your oscilliscope" articles
from thirty years ago. As I recall, they were all basically like
this one.

OK - playing on:
I got nothing. There is no power supply. No antenna interaction. No thermal
noise source. You circuit is bullshit!

Maybe we have a communication problem and should drink a beer??

Hi all -

After my first thread going from "standard" cheap parts for up to vhf frequency to a discussion about the usefulness of Spice simulator..... I try it another time hopefully get attention of frustrated co-readers:

For example the rechtifier diode 1N4007 can be used as a rf switching diode, for example as rx/tx-switch. This is because it is a pin structure diode. This type is cheap and you can get it almost everywhere. It shows good performance for the price. Surely for high-end you should do it with another type tuned to the application it is made for. But anyway it works in some circuits.

Do you know of other interesting devices or circuits good for misuse?

Best regards -
Henry

I never tried it myself, but I heard that some people abused opened memory
chips as cameras, back when CCD camera chips were too expensive for
hobbyists.

The Exide we have is configurable on output
via software, you can setup the output
via the control panel or use a laptop via
rs232 and term pgm.

the 12kva unit we have (5 years old)
is under 200 lbs w/o batteries, uses 60 12v 7ah
std cells.

Tuner Switching Diodes like the european BA244 (NOT PIN-Diodes!) work
well as medium fast Step Recovery Diodes.

Jorgen

> Such a question is stupid and incomplete.

No, Win, the question is well formed and quite complete. Sleep off the ten shots of Old Rammycackle and let's have the discussion when you are sober.

First of all, in
> cases where impedance matters, one wouldn't dare use an inch
> of lead at 150MHz, we'd cut that short, 0.1-inch max.

No, Win, neither you nor I would do such a thing. But somebody who is (as the OP posted) new to the RF world would do so without a second thought. You and I have been playing this game all our lives and take self-resonance into account without even thinking about it. However, a student new to the field (as my freshman engineering students are) makes the mistake repeatedly, even when using a decent text called ... um ... The Art Of Something Or Other. When their RF amplifier starts squeeging or motorboating, I tell them that the power supply isn't bypassed well enough, and I'll be damned if the first thing they do is put a BIGGER capacitor on the supply line.

I'll then ask them what they think the bypass impedance is and get the stock answer "1/(2*pi*f*c)". Hm, says I, how about the three inches of wire between the capacitor and the supply line. Oh, says them, that's a direct short. Straight wire doesn't have a reactive component. Hm, says I, let's see what the network analyzer says about that. Hm, says student, it says 60 nanohenries. How can that be? Mm, 20 nanohenries per inch for #20 wire sounds about right, so what does that series circuit look like? Hm. Inductive at the frequency of interest. Now, grasshopper, tell me about self-resonance of capacitors with long leads.

And
> we certainly wouldn't use an inch of pcb trace unless it was
> field-controlled with a ground plane.

That's not always an option in commercial gear, Win.

This is true whether a
> 1nF cap is involved or not. If you were to insist on analyzing
> an inch of lead, we'd insist on knowing *all* about the ground
> scene. Since you aggressively put your question without any
> relevant information about what the ground is like, and where
> it is, the question is intrinsically-stupid and incomplete.
>

If I didn't say what the ground is, then we can assume that I formulated the question without ground plane. 99% of the commercial products run this way.

> Sorry, jw\, but that's the way it is.

Sorry, Win, that's NOT the real world.

Jim

A 1N4007 can also be used as a drift step-recovery diode and as a
plasma avalanche diode. Together, two can generate a kilovolt edge
with a 100 ps risetime.

GAASfets make good fast analog switches; they behave pretty much like
jfets.

Wide-open LDO regulators make nice resettable fuses.

Ferrite beads do all sorts of interesting stuff.

Power mosfets make good heaters, and TO-220 bipolar transistors make
nice temperature sensors.

LVDS line receivers are surprisingly good comparators, and *fast*

I could go on...

The question is unclear. Any component must have a return path, either
when you measure it or when you use it in a circuit. The entire loop
determines the "lead" inductance. If I solder an axial cap, with 1" of
extra leads, onto the end of a hunk of coax, and analyze it with a VNA
or TDR, I can bend the cap leads into various fat/flat loops and push
the L all over the place.

Cadmium sulphide (CdS) LDR as a Beta radiation detector. Not sensitive to Gamma radiation which can be an advantage because it will detect Beta in presence of Gamma. You have to paint it black. Horrible temperature sensitivity but you can use another CdS as reference.

Cool. 3T regulators, 317 and LM1117 types, can be neat power amps, for
driving unipolar loads like motors and such. Sort of a follower with a
largish offset.

Hmmm, an LM1117 followed by a monster darlington becomes a
super-follower with roughly zero offset.

Tell me about it. I tried some pins to see if they would snap, and
they turn out to have incredibly mushy reverse recovery, Slop Recovery
Diodes.

I'll have to try the varicaps.

It was 1972 when I first did the 555 thing. The basic circuit was
greatly improved over the one shown in the URL. But the idea
was the same. The 555 is an interesting chip and does real well
for things like threshold detection and any form of timing or timing
related functions.

Thanks for the input! I'll get out the Fluke and download the .PDF and see what I can find before I burn the place down :) I was sort of hoping to be able to replace the stock batteries but they are so insanely expensive, hacking the box for batteries I have no use for (Still in the plastic wrap and caps on. got them in a barter) Get this- Mercedes wanted $430.00 to replace my battery for P/M- Yea right, my car now has a Optima yellow in the trunk and why a factory (much smaller and lighter too) battery would be junk after two years blows my mind.

Thanks for the info and help!

1n4007 as varactor (freq multiplier) and also Varicap.
You already mentioned RX/TX swich.
Also in PIN attenuator circuits.

Glass cased rectifiers (1n4007 in glass rather than epoxy)
as photodiode.

1n914 as 2ghz multipler (as varactor) to 100mw output.

1n914/4148 as silicon temperature sensor. (forward bias)

Base emitter of NPN silicon transistors as Zeners (5-8Vrange).
Makes a decent noise diode that way too.

Base collector of NPN si transistor as Varicap

Collector emitter of silicon transistors reverse biased as negative
resistance device.

Open GE and SI transistors are sensitive photodetectors.

Opened SCRs as photoswitches.

Allison

Google "Grekhov diode." A lot of the papers are for members only, but
this one gives the general idea:

http://www.ece.jhu.edu/~pps/ECE777/ADMAT/CircDev/Pulse-GENERATORS-SHAPERS/sub-nano-pulse1.
pdf

Grekhov discovered both the DSRD and the plasma avalanche effects in
cheap power diodes. The core of the DSRD effect is that, if a PIN
diode is forward biased for not too many nanoseconds, the carriers
don't have time to float all around the place so the charge profile is
good for a nice reverse snap. HP did the same thing in their classic
1430 12-GHz sampling head, circa 1965 roughly.

This box used the DSRD effect, in a semiconductor that one would not
expect to be used in an application like this...

http://www.highlandtechnology.com/DSS/T220DS.html

We bias the snap diode +48 volts (yes, forward direction) for about 80
ns before we turn the drive around for the snap. It was originally
designed for use in a LEAP atom probe.

Hi,

2N3055: one-time trigger diode with abt. 160v triggering voltage
[had some ones of unknown state left from a PSU that blew one of 5
transistors, replaced them with MJ15003]

various, sometimes expensive components: firecrackers, smoke bombs,
lamps (most of the time unintended ;))

old EPROMs: Lamp.Find some pins with low resistance and apply .5-2A.

the IC/transistor that was broken and took you some hours to find the
trouble:
Get 1-5 large caps (like 12 000i¿œF 350V), charge them, and apply the
voltage to the part with a very large relay.
LOUD!

Zener diodes work fine as varicaps, at least at HF. The lower the zener voltage and higher the power dissipation rating, the higher the C. As someone else mentioned, transistor emitter-base junctions can be used as either zeners (typical zener voltage around 5 volts) or varicaps.

A zener can be used as a broadband noise source. I've had the best luck with zeners of 10 - 15 volt breakdown, with around 100 uA current. Some are noisier than others, and they often have a critical current where the noise is the greatest.

Tektronix used selected transistors to generate high voltage (~100 volts) fast steps (~100 ps rise time if I recall correctly) by avalanching the collector. Some fraction of some common transistor types worked satisfactorily in this application.

1N914 type diodes can be used as step recovery diodes to generate a step with about a ns risetime -- maybe faster with a chip component and some care. This could be the basis of a broadband harmonic generator.

(nospam@nouce.bellatlantic.net) writes:

> 1n4007 as varactor (freq multiplier) and also Varicap.
That's not really a new thing, or specific to the 1N4007.

Sam Harris, in that first article about parametric amplifiers in
CQ circa 1958, goes into detail of what's required, and then
practically leaves the issue of the varactor to the end. At
the time, they were new, likely expensive, and not easy to get.
Sam had it easy, he worked at Microwave Associates at the time.
So then towards the end of the article where he attends to the
issue of the varactor, he basically says use whatever's available,
try things, and at least practice with those other devices until
you get good at it, at which point it's time for the "real thing".
I have quoted that bit in the past, but I don't know where I've
put the article to get the exact wording.

And ever since then, influenced by his words or maybe independent
thought, the magazines have been full of mention of using whatever's
available as a varactor, the results varying with the diode (or
junction, since some have used part of a transistor) and of course
the application.

And of course, there was one article where the author mentioned a lot
of hum in his six meter synthesizer that used something like a 1N914
for the varactor. He then realizes that the problem was the light
of a nearby lamp getting to the actual diode theough the glass
case of the diode, and hence modulating the VCO that way.

Take apart a couple of D cell carbon-zinc batteries.

Wash off the carbon rods. Put each in a wooden clothes pin and connect the attached ends to the mains voltage (US customers only, please).

Tap the free ends of the rods together. Move them apart as necessary. Very bright! Much brighter than you are.

Pete,
I hear ya- loud and clear. This one is even better. At 30k the P/M is to replace the serpentine belt (fully logical) I asked "How much" expecting about $30.00 He told me $220.79 Now, my car has my company name and graphic on the trunk lid, I asked the guy if it was correct and he reassured me it was and it needed a "special tool" to change it. So in I peek. Went and got a 4" C- clamp to compress a hydraulic cylinder to maintain pressure on the tensioner and installed a Gates Powergrip belt (at a whopping $14.99 at NAPA) I wonder what a $200.00 C-clamp does :)
Moral of the story- I'm not the brightest guy on the planet but that is plain theft. And people pay it, I feel sorry for them. This is why I had my ex-girlfriend's daughter take autoshop and work for me in the summer. Let some other sucker bite that hook. That in itself justified me buying a complete factory service manual and a Benz logic cartridge set for my Snap-On scanner. Hell, I would have spent that on a belt alone from the dealer.

I know it's very OT but it just leaves me angry to recall it and think I'd go for it.

All the best,

Rob Fraser

With each new vehicle I have owned, I have ordered the factory service manual(s) at the same time I ordered the vehicle. I can't understand people who whine about a $100 manual set when they just spent $30,000 or more on the vehicle. I've read every one of those manuals cover to cover several times and you learn quite a bit.

> Same question re cermet pots.

The short answer is yes, but the long answer, as always, is more involved.

Nothing is truly non-inductive -- even a short straight piece of wire has inductance. But the inductance of a conductive plastic or cermet pot is only due to the physical length of the element. That is, it's as small as it can possibly be for the physical size of the pot. That's in contrast to a wire-wound pot which has many turns and a correspondingly much higher inductance.

Whether you can use them at a given frequency depends on the particular application. If you can tolerate a wire at that point in the circuit which is the length of the pot's element (plus the distance to the external connections), then you can tolerate the pot. Otherwise, you might or might not be able to use the pot, depending on the relationship between the inductance and resistance.

Because the element length is shorter, physically smaller pots have less inductance than larger ones.

One of the MIT EE course videos on the web shows a demonstration of AC
across a pickle... it is an interesting effect. Not sure how the pickle
tastes afterward. Cooking hotdogs with AC is similar, but the pickle gives
off a much nicer translucent flickering glow. Very pretty.

Regards,
Bob Monsen

The question of the ultimate foundations and the ultimate meaning of
mathematics remains open; we do not know in what direction it will find its
final solution or even whether a final objective answer can be expected at
all. "Mathematizing" may well be a creative activity of man, like language
or music, of primary originality, whose historical decisions defy complete
objective rationalization.

LED's work both ways, as a light emitter and a photodiode.

The inbuilt colour filter can be used to distinguish between Grass and Not grass f.ex. by comparing output from a red and a green LED using white light as illumination.

Back when fiber was ex$$$pensive one often saw clever circuitry using two transmitters to form a duplex connection over a single fiber.

The USD 10 solar powered garden lamps will, with a little persuation, yield a nice solar cell well below the price of a similar unit in the shops - and - two 600 mAh NiMh batteries and a grotty circuit for switching the LED.

Hello John,

I wrote: NOT PIN - Diodes - as they wouldn't snap.

i mean Band Switching diodes for TV-Tuners like the BA244 and the BA682.

BA682 Datasheet:

http://www.vishay.com/docs/85530/85530.pdf

- and they snap! Try it!

Message-ID: <g_Dhf.233897$Il5.95863@tornado.ohiordc.rr.com>
Source record: 15886

Hi, all concerned:

For sale:

1. 80-10M Drake L-4B amplifier, sn 1010, Eimac tubes, pwr supply sn 1000, book, in good condition electrically; cosmetically, a few scuffs around the front edges. No issues with it; I simply got an amp with 160M. If you pick it up, I could demonstrate its 600W out on c-w and 1100W out on ssb. 10-day money-back warranty, provided it comes back in the same condition it leaves.

2. Meissner Signal Shifter exciter in good working and physical condition; 3.4-30 MHz, copy of book. I got it to drive a homebrew 4-400 to a KW on c-w, but that's not going to happen.

3. ESS TIME MACHINE: complete info at:
http://www.expandedspectrumsystems.com/prod2.html
I have band-filters and 9 different crystals for 40-30-20-15-10M, FLX-90, LO1 external-lo buffer, wall wart, all manuals. Got this for experimenting with homebrew software-defined-radio, also not going to happen.

4. Original service manual for Kenwood TS850SAT. Sold rigs; buyers didn't want it.

5. Before-MFJ HyGain TH7DX broadband tri-band antenna, good condition, original book.

6. Cushcraft 402CD pre-XM240 2-element 40M yagi, good condition, with CC 40M rotatable dipole I got to make 3L yagi out of 2L.

7. TMC IPA r-f deck, uses PL-172/8295A (no tube; same *socket* as 8877; chimney could have 4-inch OD-3-1/2orso-ID machined hi-temp non-conductive ring sitting on 8877 to cover over difference in tube diameters), 750pF Tune/1000pF vac variables with turns-counters in 2-30MHz bandswitched tank which has 3/8-in silver-plated conductors, 2 multi-meters, 6CL6/6146 bandswitched driver, no power supplies.

Pls make offers, and remember shipping from 45251. Antennas can be disassembled far enough to fit in those concrete-form tubes, for shipping. You know; those ones you've seen in bigboxhardware :o)

Tks for reading.

2N2369 for fast pulses.
2N2222 and even 2N2219 works, but a bit slower and they requiring more
voltage to avalance, but still < 1nS rt
The Zetex are slower but can deliver much more current (up to 60A, ZTX
415 family).

As an addition to the various mentions of common diodes as varactors there is a well publicized British design for a frequency tripler that will put out 2 watts at 1.3 GHz and uses five 1N914's in parallel.

I once built an HF transceiver that used CMOS logic chips for all functions except an audio low noise amp and a voltage regulator...with further thought those two could likely be done with CMOS logic too.

If recall Mostars had a PROM on the controller board. They're programmed using a stand alone PROM programmer. As I recall it was a big suit case looking monster.

May I ask, what frequency band is the Mostar, and more importantly, why bother. It's a Mostar. Worst Motorola radio ever!

And by varying the reverse bias through a current source (or moderately
large fixed resistor) you can make them into nifty phase shifters.

Take a crystal for which you need a constant temperature. Solder the cathode of a cheap diode (1N4148 etc.) to the crystal case. Solder one end of a moderately low value half-watt resistor to the case. Bring out the anode of the diode, the free end of the resistor, and the crystal case on wire leads and encapsulate the crystal-diode-resistor in heat shrink. Use the diode as your temperature sensor, the resistor as your heating element, an opamp/driver transistor as the comparator/amplifier and bingo, the world's cheapest crystal oven. Bang-bang or linear, your choice.

Unbuffered logic gates can make a really bad but still useful analogue
amplifier by adding feedback and bias.

The problem is that the carbon rod conducts heat quite well, so after
a while, any wooden object will catch fire :-).

>Tap the free ends of the rods together. Move them apart as necessary.

You must have quite slow fuses in 110 V land if you can do a reliable
ignition without blowing the fuse. For 230 V operation, I would
suggest using a current limiting resistor (such as a large heater) or
an inductance (such as fluorescent light ballast) during the ignition.
When there is a solid arc, the current limiter can be shorted out.

Paul

Our newspaper had an article on that.
Also, for model rockets, burning up an ordinary resistor can be used as a super-cheap ignitor.
Best---
Ron

I would put a 100 watt lamp in series thereby limiting the current. I
would shave the ends down to points so they heated up rapidly. I put
them into a hollowed out fire brick and made a cheap furnace. Of course
don't look at it; it's like looking at the sun.

PS: I was 16 at the time ;-)

hi,

sorry if you didnt like everything, but sometimes some voilence against parts that cost you half a day of time and gave you a bad headache while troubleshooting is necessary...

For more useful things, FETs actually can work as quite useful one-component HF oscillators if wires and connection points are properly chosen.With a second transistor one can build a working shortrange AM transmitter.

A rather useful (works perfectly for SMPS uses) AC current probe for a scope can be made by using a small UI cored RFI filter coil from a monitor, connecting its windings in series and terminating with a 1ohm resistor, to which a coax cable with BNC connector is soldered to.
The wire you want to measure the current in simply is fed trough the core one time.
This only gives quantitative measurements unless calibrated but can be very useful if you cant afford a real current probe.

The known resonant royer circiut used for CCFL inverters can be used for larger inverters if appropriate parts are chosen, and can produce some high frequency/high voltage with a transformer from a old TV (with no internal rectifier).
This has its uses, besides connecting it to a old light bulb that works as plasma globe or connecting both outputs to a large neon bulb [Bienenkorbglimmlampe], which simply looks very nice but also produces lots of RFI, so dont run it for too long.

FET gate drivers make nice TTL output stages for function generators, as these can drive rather high currents and are fairly robust.

If a slowly, steadily changing linear voltage is necessary (for ex. confirming the linearity of something) a 10turn precicion pot copuled with a slow syncronous motor (a old microwave oven has a nice 2.5u/min one) by some tape (so it slips/breaks when the pot is at its endpoint) works nicely.

>
>i

Too bad all you've met are the bad ones. There are a few good ones
left - but most of US have gotten out.(which leaves only the bad ones
for you to deal with).
I got out, largely, because the CUSTOMERS are unpolite,
demanding,dishonest, cheap, and generally impossible to satisfy - even
when you do something for nothing.
They book their car for 3 hours of work and don't show up, after you
have made room in your busy schedule to get them in NOW - and that is

only because it is IMPOSSIBLE to do it yesterday. Then they want you
to diagnose the problem over the phone and guarantee the price - AND
be cheaper than the other 10 or 12 mechanics they have done the same
thing to. If you can't get the parts PRONTO, they cry and complain -
and you can NOT have every possible part available - the dealers don't
either. Then they lie about what has happened to the car, because they
want it to be someone elses fault and problem, not their own.
You fix the car and they leave and stop payment on the check or
dispute the charge on their credit card. Not only that, they bad-mouth
you to everyone who will listen when at the bar, a party, or wherever,
whenever the subject of auto repair or car problems comes up - which
is ANY time. Then 3 months later, after you have fixed, say the
brakes, they come back with the wiper motor not working - and - you
guessed it - its YOUR fault!!!!
>

It just wasn't fun any more after 25 years - and its gotten a whole
lot worse in the last 15 or more years.

The current limiter I saw used a glass pie pan with pieces copper
metal on each side with salty water as the electrolyte. It would
start to steam some when in operation. The furnace was a small
clay flower pot with holes in each side with the carbon rods
sticking inside until they touched.

5471. 12 vdc distribution network?

Hi all...
I am looking for an idea or schematic for a dc power distribution box...something that will allow me to feed two vhf/uhf and two hf rigs from the same power supply and battery pack, with sufficient rf isolation.
Thanks in advance de Denton WB7TDG

As a boy, I used an electric teakettle as a ballast for a two-D-cell carbon arc lamp--worked great.

Cheers,

Phil Hobbs

A simple 1.0 K Ohm or so carbon film resistor placed across the line makes a very nice display after a couple of seconds. They also make a handy fuse to trigger a little firecracker when used as a "surprise" for some unsuspecting technician placed across his load behind the workbench when he turns it on in the morning.

I've seen pots of both types, but I think the only ones I've seen with a multi-turn helical element were wirewound. I'd say look at the shape of the pot -- if it's a flattened cylinder like a conventional pot, it's probably got a single flat element. On ones I have like that, the planetary vernier drive is obvious. But if it's shaped more like a tin can, I'd suspect a multi-turn element.

I used a 0.5 or 0.7 mm pencil lead gently torqued down across the
terminals of a regulated DC power supply. Set the current limit very
low, crank the voltage up all the way and increase the current limit
until the center of the lead starts glowing red. Due to the heatsinking
effect of the binding posts, the lead will always heat up the most in
the center, then the carbon will start to evaporate and the remaining
lead will gradually neck down in the center until it is glowing white
hot. As soon as the lead breaks in the middle, you convert from
incandescent to carbon arc lamp, which usually surprises everybody

watching. The arc is good for about 5 seconds until the voltage drop across the arc exceeds the capability of the power supply.

The Mostars originally used an EPSON "computer" as a programmer. The program was on a tape drive. Very clunky. Later on the MIB programmer was developed. I am sure you had to burn a code plug in any event.

The Mostars had a couple problems 1) The UHF ones had a problem with tin "whiskers" growing inside the helical preselector casting which would short out and detune the front end. It was impossible to repair this part as it was permanently attached to the main board. 2) the 800 MHz ones had a problem with thermal and mechanical expansion which affected the VCO helical coil which was housed in the casting called the "helical hotel" by the development engineer. This part you could solder with special solder but it would soon again fail. The symptom was an intermittent radio (no TX or RX). If you banged on it, it would start working again for days.

Apart from these serious problems, the radios were quite an advancement from the previous Maxar radios which used crystals and leaded components. I believe the Mostars were the first Motorola radios to use surface mount components and metric fastners.

>Aren't you in danger of damaging your eyes from the UV emitted from the arc?

Certainly.

I used arc welding glasses when conducing these experiments.

Some trivia:

In the silent film era, actors had eye problems due to the UV
radiation from arc studio lamps.

Most of the usable illumination from the arc lights is actually from
the glowing carbon electrodes.

"Automatic arc lights" used a solenoid in series with the arc to keep
the distance constant between the poles regardless of carbon electrode
burnout. I assume that if this is to be used with a AC arc light, both
the moving coil as well as the static coil should carry the arc
current.

Hi all,

I have a colpitts crystal oscillator with a 16.000 MHz parallel resonance crystal that I'm turning into a FSK modulator with the addition of a varactor / varicap diode. Two questions:

Originally, I had the varicap diode in parallel with the crystal. This caused the oscillation to significantly attenuate (10 dB or so) as I pulled the crystal 1 - 2 kHz. I found a reference design of a Hartley oscillator that had two varicaps in series with a resonance capacitor, so I decided to give this a try. This works a lot better, attenuating my 1Vpp oscillation about 100mVpp. Why does the series configuration work so much better?

I'm at home where I only have an analog tektronix 2213 60MHz scope (no spectrum analyzer). How can I measure the frequency deviation / pull of the crystal with the series configuration? Any ideas?

Cheers,
Chris

5484. FAQ - Is anyone interested in _REAL_ Ham Radio any more?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-26 12:35:33 UTC
From: Heinrich Hurts <aiyr.r.bean@lycos.co.uk>
Message-ID: <1133008533.449590.8800@z14g2000cwz.googlegroups.com>
Source record: 15967
Cross-posted to: uk.radio.amateur,rec.radio.amateur.homebrew,rec.radio.amateur.policy

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B

licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

If you have another crystal, build a second oscillator. Run the two into a mixer followed by a simple lowpass filter, and measure the resulting difference frequency.

Wouldn't it be easier to use a frequency counter? If one is not
available, but a general coverage HF receiver or transceiver with a
digital readout is available, you could zero beat the oscillator, note
the reading on the display, cause the oscillator to shift to your other
frequency, zero beat that signal, note the display reading and subtract
to find the difference in frequency.

The Motorola McMOS handbook (2nd edition 1974) warns about this usage
by pointing out that by cascading three such AC coupled stages, the
last stage will be saturated by the noise from the first stage.

Take one P channel Jfet and one N channel Jfet and connect them
in series so the two sources are together, connect the gate of
each transistor to the other one's drain. This is known as a lambda
connection, and if you plot the voltage vs current from drain to drain
you will see a negative resistance region, usually around 3v
(depending on the transistors). The circuit will work as a tunnel
diode oscillator up to 100-200mhz.

Did you know that a carbon arc acts as a negative resistance? Run the
arc on DC and put an LC tuned circuit in series with the arc (coil of
heavy copper tubing) and you have a powerful oscillator.

Not entirely true, the few lucky people who have been able to find
honest, reliable mechanics do tend to speak highly of them.

>
> It just wasn't fun any more after 25 years - and its gotten a whole
> lot worse in the last 15 or more years.

Remember that the people bringing in the cars in the last 15 years or so
as you have noted, are the parents (or now their children) from the
generation that has deluded themselves into the belief that mechanical
trades (dirty jobs) are somehow devoid of education and skill and have
actively discouraged their children from having any interest in such
things.

This delusion of the PYVs (plastic yuppie vermin) is furthered by the
increasing complexity of cars and the thought that the grease monkeys
couldn't possibly understand anything about computers so they must just

be swapping parts until things magically start working.

It's only going to get worse too...

To those of you who were planning to join the AWA CW contest over the next two weekends be aware that it is a members only event. I just learned so today. Be careful not to intrude and work someone.(see emails below)

I will be testing out my new Hartley and look forward to anyone else (Member or not) who want to communicate with Old Time rigs.I will try not to intrude upon their contest frequencies

This is in no way a shot at Marc who was kind enough to point out the rules to me.

As a former (for no particular reason) member who has attended the Rochester meet I have listened to the complaints about AWA over the last few years and not thought much about them one way or the other. But I now do see why people complain that they act as an exclusive group.

Yes, I know I could join again and play in the sandbox the next two weekends, but to be honest I'm not sure I care to anymore.

From: Carl Nord [mailto:chnord@comcast.net]
Sent: Saturday, November 26, 2005 12:11 PM
To: 'antiquewirelessassociation@yahoogroups.com'
Subject: RE: [AWA] Contest

Marc,

In all sincerity, thank you for the clarification as well as the others who were kind enough to fully respond to my question. There certainly were some rather unhelpful initial responses.

I will continue to finish my HB Hartley this weekend but will make sure (as a former member) that I abide by the AWA rules and endeavor not to intrude on the frequencies and work any of the AWA members.

That being said I will be on the air next weekend and perhaps some of the other non- AWA members might like to pick a frequency to exercise our OT equipment?

Subject: RE: [AWA] Contest

Hello all--

I've seen the recent queries posted about the AWA 1929 QSO party.

I guess I should jump in and try to clear this up, though I have no official connection with the AWA ham contests.

Our new AM QSO party, being chaired by Gary Carter, is the only one open to all hams. The other contests, including the 1929 QSO party, are open to members only.

The only reason you will find the dates of the QSO party on our web site is that we had to correct the wrong dates that were accidentally sent to the Journal and printed there. Frequencies, times, scoring info, etc are in the Journal but never posted on the site for obvious reasons.

Logs are sent out by contest chairman John Rollins only to previous participants or members who are newly applying for them.

Friends, this is a public service announcement only. I definitely don't want to get involved in discussions about the right or wrong of this, nor would it be appropriate for me to do so. Suffice it to say that John and the AWA have very good reasons for restricting the contest , though I can also see the other side of the questrion.

Marc Ellis, N9EWJ
Editor, The AWA Journal

We worked with a company that was developing an xray imager, and was
buying very expensive electrically conductive glass (gigohms per
square sort of range.) They discovered that certain welding glass was
identical and about 1/20 the price.

>During a power outage, which occurs frequently in Florida, I would like to
>use a battery to power some communication gear. Although the battery is 12v
>....[snip]....

Although many have suggested you should use "deep cycle" (also called
"traction") batteries, be aware that the specifications for such batteries
are DIFFERENT in that they are rated to still be producing useable power
when their output voltage is somewhat LOWER than others. If your equipment
poops out before that lower voltage is reached, you won't get all the
output you've paid for. (My TenTek 540, for example, starts FM'ing at
about 11.5 volts, so the remaining output from a deep-cycle is totally
unuseable.)

The following is abstracted from a 3 Oct. 1992 post to
rec.radio.amateur.misc by Brian Kantor <brian@ucsd.edu>:

1. Automotive starting: formulated with thin pasted plates and designed
to supply high peak currents for brief periods of time while cranking
an engine. Designed to be discharged to more than perhaps 75% of
capacity and to be recharged immediately after discharge. Typically
discharged-rated at a 20-hour rate.

2. Traction (e.g., deep-cycle batteries): made with thick pasted plates
and with very rugged separators between the plates to make the battery
more immune to physical shock and vibration and to reduce the chance
of failure due to dendritic growth during recharging. Sold for use in
electric forklifts, golf carts, marine trolling motors, and RV power.
Designed to be discharged nearly fully each day and recharged each
night. Typically discharged-rated at a 5-hour rate.

3. Stationary: made with thick solid plates. Designed to be used as
standby power, supplying minimal power and kept in a state of nearly-
full ("float") charge until needed. Can take deep discharge. Because
of the solid-plate structure, they are bigger and heavier, but their
lifetime is much longer (10 years is not unusual). Typically
discharged-rated at a 10-hour rate.

Each type of battery has a specified voltage at which it is considered
to be completely discharged; if discharge continues below this voltage,
battery life may be considerably shortened, and repeated abuse of this
nature can result in a battery which cannot practically be recharged.
Each battery manufacturer specifies this voltage; in general, the final
voltages for the three general types of batteries are:
Automotive: 1.75 volts per cell
Traction: 1.70 volts per cell
Stationary: 1.85 volts per cell

A typical traction-type cell shows the following voltages:
2.12 Fully charged, open circuit, at rest with no charge
or discharge for at least 12 hours
2.00 As soon as load is applied (internal voltage drop)
1.70 Fully discharged, under load
1.99 Fully discharged, open circuit
2.10 Beginning of charging after full discharge
2.35 70-80% charged; gassing begins
2.65 Fully charged

The following assumes 12 volt negative-grounded "automobile" batteries as
found in most cars, light trucks, and vans in North America.

Liquid-electrolyte lead-acid batteries can be recharged at any rate
exceeding internal- and surface-discharge rates and which does not cause
"excessive" gassing (liberation of oxygen, hydrogen, and steam).

In NON-float service, there are several simple chargers:
* A single-rate constant-current charger limits its charge rate to about
7% of the battery's ampere-hour capacity. Thus, for a 100 Ah battery,
the charger would supply about 7 amperes and must be able to supply
voltages between 12.6 and 16 volts over the duration of the charge.
Charging is complete when the battery reached 2.65-2.70 volts per cell.

* A simple taper charger is a constant-voltage source set to 2.8 volts
per cell with a series ballast (typically a resistor, but a choke or
the internal resistance of the supply can be used) which limits the
output current to 7% of capacity when charging is started at 2.1 volts
per cell. Again, charging is complete at 2.7 volts per cell.

* Trickle-charging (supplying 0.5-1 milliampere per ampere-hour capacity)
of a fully-charged battery can be done to keep it charged. Trickle
charging should be discontinued when it has continued for at least 24
hours and the battery has reached 2.25 volts per cell. Typically,
trickle chargers are set to run perhaps once a week. Because of their
thin plate construction, automotive-type batteries will deteriorate if
trickle-charged for more than perhaps six months. (However, using
pulsating rectified AC or superimposing a small AC current on pure DC
charging current increases battery life by up to 30%. It is postulated
that this reduces gassing, leads to more porous lower-resistance
plates, and lessens the tendency to form dendrites during charging.)

In FLOAT service, where the battery is in parallel with the mains supply,
the supply voltage must be set to 2.15-2.20 volts per cell. This charges
the battery and avoids excessive gassing, but does not serve to "freshen"
the cells--there is not enough gassing activity to move electrolyte
around and clear the beginning of deposits from the surfaces of the
plates. It is recommended that batteries in float service occasionally
(perhaps once a month) be charged to 2.65 volts per cell to freshen and
equalize the charges. In large installations, this is done by switching
parts of the battery banks out of service in rotation; in smaller systems
that can tolerate the voltage excursion (about 16 volts!), it can be done
by simply boosting the output of the mains supply.

Charging inevitably leads to some water loss due to gassing: 100 ampere-hours of a gassing charge (2.4 or more volts per cell) causes a water loss of about 1.2 ounces. Hydrocap Corp (975 NW 95th Street, Miami FL, 303-696-2504) makes replacement filler caps ($5-10 each) containing a catalytic material which recondenses emitted steam and recombines hydrogen and oxygen gasses back into pure water which then dribbles back into the cell, greatly reducing the required maintenance.

Small cermet pots should be no trouble at 50MHz, assuming you aren't going to extreme resistance values. You will always have parasitic inductance and capacitance, but if a carbon pot would work in your application, a cermet of the same size and general design should behave similarly.

Beware of the conductive plastic ones...some of those are "hybrid" pots that have a wirewound element under the plastic, to get very good linearity, and the conductive plastic provides interpolation between the turns of wire. I once used one of those to read out an angle, and it worked great, but I wouldn't consider trying to use it at RF. If it's not a hybrid (no wirewound element under the plastic), it should be OK.

You may also want to consider the amount of (RF?) current in the wiper. It's generally a good idea to keep the wiper current low, unless the pot is specifically designed for high wiper current.

Cheers,
Tom

Going the other direction, I used the elements from a toaster as a load to discharge wet-cell lead-acid batteries. It was a discharge/charge cycling test.

A 2N2369 is a gold-doped NPN, gold-doped to kill storage time and
improve recovery from saturation. I don't recall any PNP device with
gold-doping... or the equivalent.

And why, Jim, you don't comment my effort?

Maybe I'm newer to rf as you but where is the difference between a microprocessor decoupling from the power supply at 100MegHz and a rf stage at the same frequency? Truly the cpu is more challenging because of the broad used spectrum above 100MegHz.

Done PowerPC, PCI stuff and others....

A metal case of a crystal should never soldered!! This may break the
oscillation characteristics. At least you must know what you're doing here.
This type of built-in failure mode is often seen in products.
Otherwise it is interesting!

Another error with crystals is to ultrasonic the populated pcb. With the
right sonic frequency the crystals comes in resonance - cracking of parts or
wires!

There even exists LED specially taylored to the needs of doing duplex
operation.

Bob Pease of National Semi mentioned a ONE AND ONLY transistor circuit above/under voltage rail converter (with detailed theory). I cannot remember the details. But interesting if sometime a slightly voltage behind the power rail is needed. For example to power a CMOS Opamp now doing rail-input.

And optocouplers can do interesting things:

Very simple high-voltage opamp, up to 400 volts p-p.

Isolated totem-pole driver, from a few volts up to 400.

Current limiter.

Low-leakage diode, sort of like an LED painted black.

John

It is not a complete question. You could get all sorts of different
parasitic inductance values by putting the component near or far from other
metallic objects, which usually occurs to some extent in any practical
situation. Many other things will affect the answer.

You have not yet supplied anything other than a single dimension measurement
for the component. If you want the inductance, skin effect, etc. then you
would have to give me a dimensioned drawing showing the placement of the
wires, the plating material, plating thickness and the internal
construction of the capacitor. (You would also have to pay me enough to
make it worth me bothering to simulate it.) Your question is incomplete.

Well as you have not specified whether this is "commercial gear" and what type of PCB material, dielectric thickness, trace width etc. of course we can't tell you the answer. Neither could a guy who was going to answer your question by building one and measuring it. He could find one possible answer but there are lots of possible answers which differ because you have not given us a complete problem to solve.

You still gave insufficient information on the wire geometry. I would refute your claim that 99% of commercial products don't use a ground plane. The cell-phone market is in the high hundreds of millions of units this year, and is likely to reach 1 billion units per year next year, and I guarantee you that every one will contain a multi-layer PCB with ground planes and microstrip traces etc. every one of them designed using field simulators and some version of SPICE to model the integrated circuit packages and bondwires, as well as the antenna. I don't believe that this

one billion units would fit into the 1% minority of products that you think have ground planes!

>> Sorry, jw\, but that's the way it is.

Hi Carl:

The VT-127A is a good tube. It was a repackaged Eimac 100TL for radar use. Just more filament current. They were cheap after the war, but got sidetracked because the 304TL was also cheap and ran more power.

Love to see a photo when you get done as I have a few sitting in storage that belong in a rig.

It ran off 120 V. Parse the sentence as "two D-cell-carbon arc lamp." An earlier poster talked about building AC-powered arc lamps using the carbon rods from dry cells.

Cheers,

Phil Hobbs

Like some of us could lough nicely, when a new guy at a customer
(semiconductor fab/asics) of the last company I worked for had to test an
RF Chip. Another engineer came to look what the guy is doing, saw he
didn't bypass the power supply and recommended to do so. The young
engineer put a nice 2200ï¿œF electrolytic at the terminals of the
lab-power-supply.

But how to decide to switch it off? I think there you have to sample -
switch of for a short time and test. This could give a flickering
backlight.

That's what I decided 17 years ago. And I was right.

Now everybody's kid wants to be a computer tech instead of a mechanic
- and for the same reason kids wanted to be mechanics 40 years ago. 40
years ago the "gearheads" wanted to be mechanics to fool around with
their first love - the CAR.
Now the "computer nerds" want to be able to play with THEIR first love
- the Computer / Game console/ Whatever.
And they will work for almost nothing just to be able to do it. and
their method of repair??? "swapping parts until things magically start
working"

Time for a THIRD career?? (4th if you include teaching)

Unfortunately you have to log in to the site to see the drawings & photos.

I don't think it produces nearly enough current to power an opamp.

5536. freedom and independence

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-11-27 06:11:45 UTC
From: Life in America <goodwordusa@gmail.com>

Have you ever thought much about how communication is changing?

You're reading a message I posted on the usenet. The usenet is a grand expression of freedom and independence. It extends, of course, beyond national borders.

Not so long ago, all long distance communication (including news information) relied on much slower and more expensive means. But today we can enjoy the internet and usenet, communicating freely to the whole world at once. Even radio communication continues to move forward with leaps and bounds, assisted, in many cases by computer technology and even by the internet and/or usenet.

Other things can change, as well.

The same kind of freedom and independence can be had when it comes to the energy required to heat and power our homes -- and our automotive vehicles. That day, I fully believe, is coming. We can work to bring it about so that we can enjoy it now, or we can sit back and continue our bondage to big corporations (and their methods), paying way too much for power and not enjoying the freedom of having our own private sources at home.

To me, as an American, it's all about freedom and independence.

What do you think? Are the people of America still independence-minded? I mean, really?

Here in America we have a reputation for holding the idea of independence pretty high. But we need to be careful not to give too much power to corporations that love to keep a hold on our lives.

Think about it. There are the credit agencies, such as banks, credit card issuers, etc. that can end up with a lot of power over a person, or even over an entire family. There are the advertisers who work very hard to persuade us that we need to be thinking about this, buying that, and so on. And along those same lines, there are the media people who very much want to sway folks as to what we should think and feel about various issues.

But my main thought right now is the power companies themselves. The utility companies and oil companies. We tend to gripe about these guys but then we do very little to shake off the hold they can have over our entire household.

When I see the grip that electric companies and gas companies have, for example, I wonder just how much we really cherish our freedom in this country. It's not like we have no alternatives.

Alternative power is here. Some of our neighbors are using solar, wind power, various geo-thermal power, and so on to either supplement or supply their household power. The technology is here. It's working. But only a relatively small number of people are going for it.

It's possible to heat your home all winter by using passive solar, wind powered generators, and solar panels. Of course, the other big alternative is also in place and being used by a larger number of people: wood heat.

Only when enough people are switching from total dependence on the electric grid and/or gas lines to private power will we begin to see a real return to independence-minded America.

Griping about poor leadership, griping about high prices, griping about the economy -- none of this gets anything accomplished. Personal freedom & independence never comes without a struggle. The "fight" has to be inside of us before we will emerge as a free people. We can see this when we look at nations such as Iraq. Why can't we see it in ourselves?

Real freedom cannot be given to us by other people. Politicians will never be able to do it for us. It must be earned, forged, built with our own hands. That's demonstrated in the history of our own nation. It's just as true today as it ever was.

Anyway, just thinking about these things.

Jim

Hi Ivan,

Yes, I'd expect it to say its a hybrid pot in the data sheet. They tend to be quite expensive.

What are you doing with this particular pot? It always helps in giving a useful answer if we have all the relevant information, and "50MHz" isn't a whole lot of information.

Cheers,
Tom

Tom,

it is the old good ARRL noise bridge. It has a pot in its output bridge
circuit.
I changed the layout of the elements a little from what is in the Handbook,
and found it works reasonably well up to 50MHz. The signal is still audible
on 2m, but I did not concentrated on evaluation of the circuit on that band.
The original question came up because I had unacceptable results with the
carbon pots (they are not good at their minimum level). My hope was cermets
or plastic ones may have better stability.
Unless the pot is of a wirewound type, parasitic inductance of the element
could be compensated as described in the article.
And because the null can be very sharp, a multiturn pot would be of a big
help.

My best regards,
Ivan

When I was a teenager and my brothers started bothering me with their loud TV, I took a 220V relay, put one of the coil leads through its normally closed contact group, and plugged the relay into the mains behind the wall where the TV was. Made an exelent TVI/RFI generator, I thought the TV is going to blow up.

Ok, you found the skeleton in the closet. :-) You can not use
this method to switch it off - but it is not required in most cases.
Think of a cell phone - the backlight goes on every time you press a
key, and it is going off after 10 seconds.

When I was a lad, old dry cells were a source of interesting scrap,
carbon rods, zinc flashing, brass strips and brass terminals.

Are zinc-carbon cells still sold today, or are the AA, A, C and D
cells made up of more insidious (and poisonous) compounds?

The metallically-sealed cells look a little more daunting
than the bitumen-sealed zinc cans of yore.

What do we get when we rush down to our local hardware stores
apart from fork handles?

PS. I'm interested in getting hold of one of those wet Leclanche
cells, the sort with the baekelite moulded tops, that were
used to power door bells. Anybody got one for disposal? ISTR
that there was no depolarising agent fitted which served a useful
purpose - that of preventing annoying long presses of the bell-push.

> Are zinc-carbon cells still sold today, or are the AA, A, C and D
> cells made up of more insidious (and poisonous) compounds?

Just don't start prying Li-Ion cells to bits. They're rather nasty if you manage to puncture them.

I have two editions of "The Boy Electrician". The 1940's edition
is full of doing interesting things such as you describe, and
includes info on setting up your own X-Ray tubes with
attendant HT supplies!

The 1960's edition has been fully sanitised (Odd, because if
predates the Health and Safety paranoia by several years) and
all experiments revolve around 9 volt batteries.

Seven or eight years ago the gas gauge quit on my dad's jeep. He
took it to the dealer. The changed the sending unit. Then they changed
the gauge. They had it over a week and still hadn't fixed it, so he paid
them over $400 to get it back. I took a look at it and found the problem
in 15 seconds. The lug on the ground wire to the sending unit had
snapped, and the wire was hanging down, in plain sight. A new lug took a
few minutes to install and it worked fine, till he traded it in on a new
car a few years later.

Its like the days when there were real TV shops. The techs knew what they were doing, and went to every available factory school to keep up with the new designs. Most people thought you just shoved tubes in till the set worked, and that it was criminal to even want to make minimum wage. They were rude, ignorant, and price shopped for the cheapest service calls. Well, guess what? The cheapest service calls were the fly by night operators who worked out of the trunk of their car, or in one case, a dirty old hippie in a VW van that reeked of marijuana some. It was rare to find a good customer who understood that it took time to repair something, and some parts took time to find.

We had a "Customer" take us to small claims court because we charged for an estimate. He claimed that his mechanic didn't charge for an estimate, so we had no right to, either. He and the judge had big smiles on their faces as they told my boss he was wrong. My boss plopped a RCA CTC38 series chassis on the Judge's bench and said, Well, in that case would you mind telling me what's wrong with this set? The judge started yelling that he had no idea what was wrong so my boss asked, If you can't tell by looking, how can we? We have to find the problem, replace the part and make sure there are no other problems before we can give you an accurate estimate. He won the case.

I started computer repair on the old Commodore 64. A scope and good soldering skills were a must. I built a test bed with ZIF sockets to test the different chips so I could verify that they were bad, and to test new chips when they arrived for wherever I could buy them. Now, I'm old and disabled so I repair PCs as a hobby. I collect dead and half stripped computers and build working systems from the parts. They are given to the local "Vets helping Vets" program so they can be given to disabled Veterans who can not afford to buy a computer. It gives me something to do for a few hours a day, but I really miss building TV stations and telemetry equipment for the aerospace industry.

Most of the audio section was done that way. But the product detector had low impedance output and the CMOS amp was too noisy at 50 ohms. A transformer might have done the job but a common-base amp seemed more practical and less prone to picking up hum.

Steve

I think you mean they are the "children (or now parents)"- this type of
mental dyslexia is disturbing to the meticulous reader.

I like that- PYV- good acronym- or "awesome" as the PYV say.

The moral of the story is that you are PYV. All the electronic boards are LRUs in the mechanical trades and there is no way that repair could be cost effective any other way, parts are way below labor costs. In the case of a lightning strike where one board has failed, it is good practice to yank *all* of them and be done with it. You are getting *new* boards at reasonable markup, you pay a single labor charge, and there is no possibility of less than a durable fix or additional damage being done due to faulty drive. I can see the HVAC tech breaking out the oxy-acetylene torch to solder components...too funny.

A 741 op amp was used as a comparator driving an opto-isolator
triac driver. A triac then controlled the heater. The op amp
compared the voltage across the diode to a fixed voltage provided
by a three terminal regulator and a 10 turn pot. The wiper of
the 10 turn pot was connected to a single turn pot that
then provided the temperature setting. The two pots in series
were needed because the range of adjustment was very small
(the voltage across the diode varies with tempature, but the
change is small over the range we are interested in for
a heater controller.)

I have a couple of 100xx also and some tunning capacitors and coils and
transformers etc.
I have been keeping these for an old time rig that probably will never
get built.

Anyone want to build a tube rig? I already have too many projects.

They published a 1960's edition?!
The last version of TBE I saw was published in the '50s and
still had all the 'nasty' stuff. This version had a one tube
regenerative receiver using a 1H4G tube that was nearly obsolete
at the time. In fact, A. Morgan also published a set of books
called the Boy's 1st - 4th books of radio and electronics.
In the first book he had a similar radio, but in latter editions
of that book the tube was changed to a 6 volt 7 pin mini type.

Lindsay books (www.lindsaybks.com) is now selling a reprint in paperback
of the 40's BE, which has several radios using the type 30 tube
(same as 1H4G with 4 pin base). Except for the sections on radio,
the 40's and 50's editions are the same.

I understand that the old design cells are still made. If you buy the
cheap cells ($1.00 a dozen or so)
then you get the old style. But if you buy Alkaline batteries you get a
cell that has the Zinc in the center
and Carbon around the outside. Most of the Zinc and Carbon is powdered
in the Alkaline cells

No, I meant it in the order it was in. The PYV parents came first 15 or
so years ago, followed later by the children of the PYVs once they were
old enough to have cars needing repairing.

Shrug...I spent $65 to have my truck run though the computer
diagnostics. They couldnt find the problem, suggested some high dollar
repairs..shotgun approach.

I replaced the badly worn distro cap and the rotor. Ran fine after
than.

Im starting to think that there are more button pushers than actual tradesmen in auto mechanics.

Gunner

"Pax Americana is a philosophy. Hardly an empire.
Making sure other people play nice and dont kill each other (and us) off in job lots is hardly empire building, particularly when you give them self determination under "play nice" rules.

Think of it as having your older brother knock the shit out of you for torturing the cat." Gunner

Back when I was living in a college dorm, the guy in the next room had pretensions of being a musician - specifically, a drummer. His way of "practicing" was to turn up his stereo - really loud - so he could feel the bass, then put on headphones (so that the highs wouldn't hurt his ears) and then drum along with the music.

Needless to say, this did not make him popular with me or my roommate, the people on the other side of his room, or the folks downstairs (or, I suspect, people in the next county). Numerous complaints were filed; he kept on drumming.

The guy on the other side realized that the drummer's stereo was plugged into an outlet on one side of their shared wall, and that he had an outlet on the same circuit. The next time the booming started up, he plugged his old fluorescent desk light into the outlet, and then started vibrating his thumb on the pushbutton make/break "start" switch.

BRRZZBuzzzBZAP.

Stereo goes off suddenly. Two minutes of blessed silence. Stereo goes back on and the drumming starts again.

BURZZRfffBUZZT.

Lather, rinse, repeat. Eventually, the drummer gives up for the day.

I understand that the drummer never did figure out what was wrong with the stereo, despite two trips to the repair depot. He left the dorm at the end of the quarter (I suspect he was "asked" to depart by the Powers That Be) and we could sleep and study in peace once again.

Many years ago, I lived on the 2nd floor of a 3-story apartment building. A guy moved in above me who worked some strange shift such that he generally slept during the day, and at night, when the rest of us were trying to sleep, he'd blast his stereo until the early dawn. I tried reasoning with him a few times, but when it became evident that he didn't care about anyone but himself, I decided that he needed a taste of his own medicine.

I wired up a 555 timer, a driver transistor, and a 12-volt solenoid that I had harvested out of an old VCR. The body of the solenoid was fitted with a couple of alligator clips, so that the coil could be attached to grill of a heating duct near the ceiling of my apartment. Every half minute or so, (adjustable with a pot) the timer would fire and the solenoid would contract, making a loud, obnoxious ker-chunk that resonated through the furnace duct.

Whenever I left the apartment for work, I'd install the gizmo on the vent, and let it run all day while the guy upstairs was trying to sleep. The beauty of it was that the guy above could not complain about anything I was doing, he could only complain that the "furnace was making strange noises" that kept him awake.

A couple of times the management asked to inspect my furnace, and of course, I let them. Needless to say, the gizmo was turned off and had been removed from the vent in preparation for their visit.

Eventually, in true Pavlov-ian fashion, the guy upstairs learned that the strange "furnace noises" seemed to coincide with the abuse of his stereo. He noticed that when his stereo kept me up at night, the "furnace" kept him up during the day. Hmmm..... An unspoken understanding was reached and everyone lived happily ever after.

I had a mid-90's Chevy S-10 with antilock brakes. One day, the brakes made a funny sound and the service light came on. I noticed that the brakes were not behaving properly.

I took the truck in for "Mr. Goodwrench" to take a look. They told me that I would need a new antilock computer and the cost was something on the order of $1000. I told them to forget it.

I limped the truck home and later, curiosity got the better of me. I jacked up the truck so that the front wheels could spin, and then I went hunting for wheel rotation sensors. Connecting my scope, I could see a nice, clean sine wave coming off the front right wheel. The waveform from the front left wheel, however, had a a very irregular shape that was much lower in amplitude.

I purchased a new rotation sensor for $75 bucks, pulled the wheel and brake disk, and installed it. Everything worked like a champ after that.

It appeared that the old sensor had been struck by rock, and the core of the sense coil had probably been fractured. I was left to wonder how it is that, without the benefit of factory training, documentation, or diagnostic equipment I could troubleshoot and repair the problem when the dealership could not....

thank you, then I suppose the 2N3905 oder 2N2905 are fitting for a large
signal amplifier.

Wow Myron,
That was the most comprehensive battery post I ever seen. I makes me want
to add (oh boy, some more drain) a circuit that will cut off the battery
when a small percentage down. Now... how will I do it?

Unfortunately most alternative energy sources are efficient on a local
basis only.

Alcohol is expensive to make and low octane. Hydrogen is plentiful
and very expensive to make and store although metal sponges may offer
some hope.

Methane recovery from land fills works very well, but again on a
localized basis.

Over all, at present, nearly all alternative energy sources are much
more expensive than gas and contrary to the sites I don't see that
changing any time soon.

Wind and solar are very localized. Here in most of Michigan, neither
is of much use over most of the area. Solar is expensive to install.
Depending on your climate it may be expensive to maintain. Our wind
average is ideal for wind generation, with the exception that the wind
alternates between very high and nothing, neither of which is
practical.

The one good thing is they do help reduce our dependence on foreign
oil, but in general they have a very long way to go to become cost
competitive.

Source record: 15804

...usually, a crystal oscillator has a quite high voltage developing
across the crystal AND the varicap which is in parallel with it. this
AC voltage adds and substracts from the DC control voltage, causing the
instantaneous voltage to change and thus vary the capacitance. the net
result is a damping effect of the oscillations' amplitude.
when you have two diodes in series the AC is causing the voltage to
increase on one diode and decrease on the other. being in series, they
compnesate each other in some measure thus reducing the effect.the
additional cap you mention is more of a DC blocking capacitor, more
than anything else.
As for frequency measurement, the only real way is a counter. lacking
one, zer boat the oscillator on you radio, change the tuning voltage to
the other extreme and guesstimate the pitch of the beat note. nothing
much else you can do, except, may be, see if it works OK when
modulated.

An honest mechanic would first tell you to tighten the fuel cap
before they look at it and charge nothing for the advice. This is
a *very* common proglem; BTDT. Here, most of the bigger auto parts
stores will read out the computer as a free service. They won't
reset the codes, but will tell you what the computer "thinks".

OTOH, my '93 Eagle Vision had an intermittent in the flywheel
sensor (no RPMs -> no ignition/fuel) that didn't show up on the
computer until it failed with the computer attached. The shop
drove the thing for a week before the failure occured.

Thanks, but all I did was archive and repost! (Although I did incorporate
it in a much-bigger battery "article" I've been accumulating from many
sources [including one video from, IIRC, the Ford Motor Company on the
batteries they put in Ford vehicles] for my own use and for sharing at
the local ham club.)

If **I** had to do that, I'd use a plain ol' 555 "timer" IC as a threshold
voltage detector and use it to drive relay(s) to do the cut-off, but more-
modern designers would use a little more circuitry to drive an FET.

And you need to ask why??????
Anyone with half a brain got out of the business 15 or 20 years ago.
ANd not too many with half a brain or more are getting into the
business over the last 20 years.

When I started in the late sixties, it was the lowest paid trade - bar
none.
When I taught the trade in the seventies, the attitude at the schools
was "he's too dumb to make a scientist, plumber, electrician, or
machinist out of - and too smart to be a lawyer, so we'll put him in
Auto Mechanics.

So I had to teach them electrical, plumbing, physics, machining, math,
and all the rest to make mechanics out of them.

Depends heavily on the tech who looks at it. I was handed a truck a
couple of weeks ago that someone had spent all day trying to
troubleshoot. No cruise control, no Jake brakes. He'd thrashed around
for eight hours, running diagnostics, checking sensors, even popped the
valve covers to check the brake solenoids.
I found the broken clutch pedal return spring in less than a minute.
$12 part, five minutes to install.

In many cases these mechanics are not so much dishonest as ignorant.
They just plain do NOT know how to troubleshoot.
The ones that have the manual, and know how to read it (that is an art
in itself - particularly with FORD Manuals) they blindly follow the
pinpoint tests - which can send you in 15 interlocking circles at the
same time if you do not use your PDT (Primary Diagnostic Tool)
(Otherwize known as the brain God gave you). Blindly following the
manual can cause you to replace many parts that are not part of the
problem.

In order to effectively troubleshoot today's systems, you MUST have an
understanding of how it is SUPPOSED to work, so when it doesn't, you
have a clue as to why.

I've seen several speakers where there was a light bulb, in series with
the tweeter, as a power limiter

Expect more nasty weather... it's heading your way. Here on Saturday
night... very windy, Sunday night plunged to about 25ï¿½F.

Got in the wife's car on Saturday and backed out into the street, and
commented, "Why is the AC blowing warm air?"

Wife replies, " I don't know, it did that for awhile yesterday, too."

I pushed the Ambient button on the dash... it was 65ï¿½F outside...
winter has arrived in Arizona ;-)

We burned a log in the fireplace last night also. It was sufficient
to keep the inside temperature above 68ï¿½F. Don't know yet if I'll
need to turn on the heat this year or not.

Yeah, I went to Midas for a "$39.99" muffler. When I finally got the
car back, the bill was over $400.00. I should have sued the bastards.

Don't ever go to Midas, and tell your friends, relatives, and what the
heck, people on the street: Don't go to Midas - they're thieves.

Thanks,
Rich

One time I used an old Iron as a dummy-load for a 230V/1kW TRIAC power
control circuit (we had it in the lab for improvised BGA soldering). To
"satisfy" the thermostat I used a 30cm room fan.

I once owned a Knight transistorized amp that used incandescent bulbs in the output stage to limit current. When you had some brighteness, you had a problem.

I remember that it was the very worst-sounding amplifier that I ever owned.

You must have to cook the bejabbers out of them - I chopped up a dill pickle once into a stew I was concocting from leftovers ane expired stuff in the pantry, and it was kind unnerving every time I bit into a pickle chunk. Or maybe I didn't chop them finely enough. (more like I "cubed" them.) My Mom [RIP] used to put weiners and sweet pickles through the meat grinder. Simultaneously. I refused to even taste the stuff. ;-)

Thanks!

Recipe? For _STEW_??!!?????

You brown some meat, throw it into a pot with some veggies, add enough
water so it doesn't boil dry, cover it, and simmer it until it starts to
smell like food. ;-)

(Then again, I used to watch Mom cook. ;-))

Cheers!
Rich

Heh heh. I have a Knight kit-built amp that glows too, but that's a bias problem in the tube output...

...No, I don't use it regularly...

I think I remember something like that, maybe with ground beef.

Here's a recipe for 'Solianka' soup with dill pickle, pickle juice and
a bunch of hearty stuff. They might make it differently in Tartarstan
though (home of Tartar sauce, I presume):

http://soup.allrecipes.com/AZ/SoliankaRussianBeefSoup.asp

From other recipes for Solyanka (or however it's spelt/spelled) the
common factors are beef broth, pickles, olives, capers, onions, garlic
and some kind of meat-- other winter veggies are fair game. And a
dollop of sour cream.

Best regards,
Spehro Pefhany

Well, Galya's was all vegetable except for a cube or two of bouillon (I
don't know what kind). She had chopped the vegetables so finely that I
didn't notice the pickles until she showed me the jar she took them from
(I couldn't understand her description of "spiced cucumbers" :-).

I don't know how she made it, since I had put her son, my step-grandson,
to work with me raking a ton or so of oak leaves from my six 100+-foot
trees.

Even a lovely season like autumn has its price.

John Perry

Maybe 2N4261 ? Have not looked into the datasheet, but as i remember,
i have seen them sometimes in complementary with the 2N2369

You mean Labskaus?
http://en.wikipedia.org/wiki/Labskaus

Here in Bremen/Germany we usually leave away the fish and use just Corned
Beef (the brazilian Corned Beef is just fine). And sometimes, you find
diced pickles in it. Tastes even better, then.

I know how to make stew, without a recipe, but it wouldn't taste like
Russian stuff with capers, olives and pickles. I guess you have to
make it only from stuff that would be available in the Russian
countryside in February, and spice it up with the appropriate
crunchy/salty bits.

Sounds basically like corned beef hash with sides of fried egg, pickle
and perhaps rollmop herring. Though more gooey with mashed potatoes
used rather than chopped.

During my time in the german military, I had some courses of instruction on a base near Hamburg. One day they served Labskaus in the staff canteen there. That stuff looked just like that on the wiki photo.
This was the event when I learned why they had roller blinds made of solid steel between kitchen and refectory.
One of the comrades said: 'I won't eat this. That's food for pigs!' And he threw his dish into the kitchen. Most others followed.
The officer of the guard, whom the cooks called after closing the roller blinds, had to draw his gun and shoot in the ceiling to calm the riot down.
Since I had been near the end of the queue, I had no opportunity to try this Labskaus. I still don't know what it does taste of.

Best regards,
Gï¿½nther

It may not be as common as the 2N7000, but it has fairly similar specs:
http://www.zetex.com/3.0/pdf/ZVP2106A.pdf

I'm told that 'zero beating' typically has accuracy not much better than some tens of Hz due to the limited lower frequency response of the human ear... has anyone tried zero beating a signal from above and below and taking the average to get what might be a more accurate frequency estimate?

I've always been led to believe that this wasn't a bug, but a feature.
Really! (E.g., you can often get away with one diode when you'd otherwise
need two if the things actually recovered quickly...)

When the frequencies are close, a CRO is a great zero beat detector.

Yup.

It's a bit easier if your crystal happens to be on a frequency which
lets you zero-beat against an AM-modulated carrier signal, such as WWV
(during the early part of each minute, when it's sending a tone
burst). You don't have to try to pick out the beat frequency
directly... instead, you listen for the tone to waver in and out, and
tweak for the slowest wavering.

It's not hard to get the zero-beating accurate to within 1 Hz or
better with a bit of patience.

Use an analog comparator to drive a LED so you can see the difference
when you can no longer hear it. Add a counter if you want to get fancy,
and you can count the number of beats per minute, hour or even day.

Ed from Ed I just picked up a apc bk500. I charged it most of the night
and the voltage only shows 98 volt on battery. The instructions on the
internet show some sort of cd disc for windows which I do not have with
a good battery can I just use it as it is for a usp for the computer.
no alarm led lights on and it appears to be working fine thanks Ed

Citizens of Liverpool are called 'Scousers' (when they aren't called worse), this derived from the local delicacy lobscouse. Corned beef stew with chips in it.

I'm not aware of the inner workings of these things, Ed, nor have I put an AC voltmeter on the output, running off the car battery, to see what actual voltage I'm getting. The computer runs fine off of it but now you have my curiosity going.

My homebrew receiver (see QRZ.COM, W0IYH) has a 1.0 MHz xtal osc and a divide by 10 to 100 kHz. I can get the beats from WWV at 10 MHZ and set to zero beat using a front panel (lower right hand corner) trimmer capacitor and ON/OFF switch. The 100 kHz marker is then within several Hz on any ham band, including a possible small doppler shift of the sky wave signal from Colorado. The accuracy and short term stability are more than good enough for 100 kHz harmonics in the ham bands. In CW mode the zero beat is offset by 500 Hz and I can use an audio freq counter to get a 500 Hz count. The 1.0 MHz freq goes to a jack on the back of the rcvr and I use that to set the reference freq on my Heath freq counter while I am at the same time monitoring WWV at 10 MHz. A digital counter in the rcvr indicates signal freq with a 100 Hz resolution. To avoid possible accumulated frequency counting errors I stay 1 kHz away from band edges.

The Roman legionaires a long time ago learned that an army marches on
its stomach. Since Roman soldiers would march 30 kilometers per day
they had to keep fit and good nutrition was a primorial concern for
the generals. It isn't suprising then that soldiers are ready to riot
and mutiny over their grub with such a longstanding tradition.

A step-recovery ("snap") diode works on the principle of stored charge in the diode. During the forward biased half of the AC waveform, the diode is a very low impedance and it stores excess charge; during the reverse biased half of the waveform, the diode remains a low impedance until the stored charge is depleted, at which time the diode "snaps" into high impedance. This snap acts much like a spark-gap transmitter, in that a tremendous number of higher order harmonics are generated. In general (and there are ways to enhance this), the power available from any harmonic is around 1/n * Pin, where n is the order of the harmonic and Pin is the RF power input to the diode.

Biasing the diode simply varies the point on the reverse cycle of the AC waveform where the diode snaps. For maximum power, you try to get the diode to snap at the peak of the waveform. However, by varying the diode bias, you can get it to snap before or after the peak of the waveform. Generally you can get it to snap plus or minus about 30 degrees about the peak before the snap action degrades.

60 degrees of phase shift is nothing to talk about unless you are working with the 10th harmonic, which means a phase shift of 600 degrees. Now you've got something to work with.

Jim

Well, then the cook is to blame, not Labskaus per se. Go to Hamburg
and visit the "Old Commercial Room". I guess they make still delicious
Labskaus.

Looks a lot like ordinary corned beef hash to me, if a little less
coarsely chopped.

But I wonder why they serve it with one of these?

>curiosity going.

It might be worth re-checking the AC output voltage using a voltmeter
which reads "true RMS". Most inexpensive voltmeters actually read the
peak voltage, and display an RMS value calculated based on the
assumption that the waveform is sinusoidal.

A lot of backup power supplies use inverters that create a distinctly
non-sinusoidal waveform... it's sometimes a square wave, and sometimes
a "stepped" waveform which crudely approximates a sinusoid.

It's entirely possible that the APC BK500 creates a non-sinusoidal
waveform, whose RMS value is close to the nominal 120 VAC, but whose
peak voltage is lower than that of a true sinusoid having 120 VAC RMS.
This could cause most inexpensive voltmeters to read a value that's
too low.

the problem is, that it is an rf-transistor and can't be driven at
30V/0.2A, I found a complementary in an old table KTT, the 2N2894A, but
it also has max. 12V, so I find no other than the 2N3906.

If I simulate with the 2N3906, the frequency response is not worse than
with the 2N2894A.

>to get what might be a more accurate frequency estimate?

On zero-beating very low beat rates: The only perceived problem is the stability of the receiver and manual control of finding an "exact" zero-beat. Other than that, cranking up the audio level will let you know - by the background hiss intensity changes during zero beat - when the zero point is reached. With manual tuning and a crystal-controlled BFO that could be done to about +/- 0.1 Hz if the receiver is kept at an even temperature and power line voltage kept stable. [the metrologist's patience is a factor there as well]

There is a problem with modern receivers using PLL or DDS sub-system tuning: The resolution of the control system (typically 10 Hz on HF receivers). That limits the precision of zero-beating...unless the beat difference itself is measured with a counter.

"Time interval averaging" has been used for 3 decades in frequency and time interval counters to increase accuracy limits caused by the +/- one count on the display. Statistically, that can be improved by a factor of the square-root of the number of times it is measured. For example, taking the square-root of 100 measurements will increase the accuracy by 10 times; 10,000 measurements will increase by 100 times, etc. That averaging is automatic on base ten displays in modern frequency counters made since the 1970s.

Example of determining accuracy of frequency standards beat against WWVB on 60 KHz: An early H-P WWVB receiver and strip-chart recorder read-out for phase difference against WWVB. A nice little overlay scale was provided to lay on the strip-chart recording.

Find the slope of the phase comparison plot on the overlay and
determine the error of the local standard down to Parts Per Billion
no problem. [extreme example of "low-frequency" zero-beat...:-)]

LenAnderson@ieee.org

Two years in Standards Lab at Ramo-Wooldridge Corp. in early 1960s.

If you have the right kind of AGC you can listen to the noise getting
stronger/softer and go for the slowest variation -- this will get you as
fine a zero beat as you have patience for.

National Semi's (now Fairchild) 2n5771 was a gold-doped PNP.
ft>=850MHz. For avalanche mode one might try the lower-Vce-rated
PN3640 (12v), or PN3639 (6v).

I might even have notes on this. I tested/compared various BJTs in
avalanche mode some years ago, trying to find the "best." ISTR picking
the 2n2369, both because it was fast, and because it avalanched
reliably where other types wouldn't.

Hi, James,

Interestingly, the best avalanchers aren't usually super-fast
transistors, but old klunky things. The Zetex avalanche transistors
have lowish Ft's and are made in Russia, maybe on an old process.

How can you expect someone to make an offer on a piece of equipment they have never seen? All we have to go on is your description. You see the equipment, you know it's condition, you know how it performs, you know what you will take for it - why not just say? Or are you hoping for the proverbial sucker?

Howdy John,
I was unclear: by "...it was fast..." I meant the 2n2369 was one of
the devices with the fastest avalanche edges.

Digging through some of my notes, I don't see the BJT comparison, but
a 2n2222 biased to +100Vce, banged / triggered by a 74HC-series gate,
gave synchronous 750pS risetime pulses. Not very impressive, really,
though good for higher-power stuff than I needed.

Interestingly, I found a 74AC00 driving an MPS2369 was faster & less
trouble: 360pS fall (turn on) time, & 570pS rise (turn off) time, and

no nasty high voltage supplies. It was possibly even a little faster than measured--at 360pS I was pushing my poor little 7S14 1-GHz sampling plug-in pretty hard.

Best,
James

An old Raytheon datasheet says the 2N2894 was doped with platinum.

BTW -- in AoE, we list the 2n5771 as a PNP complement to the NPN
2n5769, both 15V plastic versions of older metal-can parts.

I was thinking of the "bismark roll", which I had thought was some kind of jelly donut, or "bismark donut", which would be like a jelly roll.

But I can't find a single reference to the thing except at the wikipedia disambiguator page, and all it has is the blurb, something like what I said.

Oh, well. :-)

Thanks!
Rich

Thank you Jim for your longly explanations. I already knew the charge storage process, but the phasing aspect was new and interesting.
My question about phase delay was in another direction.
To be concrete:
How to delay (=phase shift) a 145MegHz signal (mostly sinus waveform) with a snap diode? After reading your explanation I cannot see how to achieve a non-snapping action here. Maybe that would work with the diode if you modulate it with dc current getting delay in the ps timescale.
Another question would be if it possible with the snap diode to make a power amp in some form of ringing oscillator. Of course, it should be modulable at least with FM.

I have also been advised to look into NEON LIGHT WIRE. Working
voltages in the 7000-9000 V range, bearkup must be much higher.
Available in high current versions as well. For a big neon sign, 1A @
7000V is not unusual.

I suspect CRT wire is still better insulated, but neon is more easily
available.

Note the multi-group posting.

For 18 years, I've been reading newgroups on Unix (or Linux) machines,
first using "rn" (readnews) and later "nn" (netnews), but now my ISP
(Kansas State University) has notified me that, because their news server
is getting old and because I'm one of only a very few users, they are
dropping the service as of 28 December.

So I need to find an alternative way of getting my daily "fix";
I sure hope someone has suggestion(s)!

If you like using the old rn, nn, and tin servers, get a shell account
from Panix. You can telnet or ssh in from anywhere in the world, type
"rn" at the shell prompt and go. And it's ten bucks a month and the
tech support is better than you've ever had from Computer Services at KSU.

Hi,
does anybody know if coating on Amidon toroidal cores has any dielectric properties, such as a particular breakdown voltage rating, or it is not meant for electrical insulation.

Thks

5654. Need to build 100 mW UHF power amp

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-02 06:27:23 UTC
From: Neil Preston <npreston@nospamgeocities.com>
Message-ID: <fPRjf.25242$dO2.3666@newssvr29.news.prodigy.net>
Source record: 15787

I want to be able to send a UHF TV signal (400-800 MHz) from one end of the house to the other. I have a UHF digital PLL modulator with an output level of 7dBmV minimum, and would like to use it to feed a small linear 100 mW "power" amp to a 1/4 wave whip.

I don't think I'll find such a critter very easily, (if at all) so I would like some suggestions as to how I might find resources to build one. (Of course, a pre-designed schematic and PCB layout would be ideal!)

Anyone have any suggestions as to where to start? (Besides Google... BTDT.)

Neil Preston, CET

Source record: 15788

My suggestion is don't start !

In most countries transmitting at that power level and frequency will require a radio station licence, which will not be available to you anyway, since it is within the UHF TV band (unless you own the TV station you wish to retransmit).

Within the confines of a house the best and cheapest way to send a TV
signal is via a low cost ready made 2.4 GHz system with a choice of a
number of freqs in the 2.4GHz band .
If you also have a wifi system through a wireless ADSL router you
must ensure that the freqs for both systems are well apart.
I do have these 2 systems in operation without interference problems

Frank (Highland Ham)

Amidon dust-iron cores are not uniformly coated.
It is just a colour-coding paint, sprayed on.
Otherwise the paint may just as well not be there.

I'll take a wild ass guess that you don't want the signal propagating
equally in all directions, but that you have a particular signal path
in mind.

Putting something as simple as a corner reflector (or a parabolic
reflector) behind the transmitting antenna can give you an effective 10
to 12 dB signal increase. Focusing the receive antenna helps as well.
If you build a pair of reflectors, your total investment will be on the
order of 75 cents. Look at freeantennas.com for templates you can
scale for your frequency. Reflectors let you focus the rf energy where
you want it.

If you *really* want to use an amplifier, search ebay for minicircuits.
They make prepackaged rf amplifiers, along with a lot of other rf
goodies. But you're going to have to adapt your gadget and antenna
system to interconnect with 50 ohm lines and SMA connectors. And
somehow I doubt the output of the transmitter is spectrally pure. It's
bound to have *some* filtering in it (one would hope), but when you put
it into a very wideband amplifier (such as the MiniCircuits ZFL-1000GH)
that amp will amplify *ALL* the signal -- fundamental, spurs,
harmonics, you name it. And do you know what the output level of your
transmitter is (into a 50 ohm load)? You need to know that to properly
select the amplifier.

Try the reflector aproach first.

There are legal issues to doing that in most countries. Besides 100mw
is a lot of power for maybe 100ft. You need maybe 10mw and thats a
lot less of an effort. Also if you target isn't moving a corner
reflector at each end will make a big difference.

One last thing most TV system antennas are dipoles and horizonatlly
polarized TX and RX antennas should have the same orientation.
Ignore the gastly bad monopole that comes with TVs for UHF.

And, using Google, you run the risk of being killfiled by a Great Many
usenet denizens because of the gawd-awful defaults Google uses for
follow-ups in its posting configuration. But, then, you knew that...

So, you being a *nix user, I can't see you getting excited about doing
usenet 'text work' with a bloated cartoon interface. I'm a *nix user,
too, and I can recommend Individual.net (http://news.individual.net/).
It's is the follow-on/re-incarnation of the free news.cis.dfn.de. It
costs 10 Euro per year and it's well worth it. I used the online sign-up
and paid via the FirstgGate (http://firstgate.com/EU/en/info.html)
service they use.

Now, if only slrn could score on top-posters. sigh...

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B

licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

Hi, All;

Thanks for the responses so far.

The intent is to produce a device that will operate within the limits of Part 15 of FCC rules for unlicensed radiators. Somewhere in the back of my mind the 100 mW figure floated to the top, probably as a result of the old 100 mW unlicensed CB walkie-talkies we used to play with as kids.

It is probable in this case that a 10 mW output to a corner reflector at the transmitter site will suffice. The target is a standard residential TV receiving antenna connected to a household distribution system. The received signal needs to be large enough to drive a number of splitters and lengths of coax. This would allow us to view the image on any TV in the house.

The exciter is specified to produce a 7 dBmV output into a 75 ohm load, which I calculate to be about 2.2 mV or 67 nW. I don't believe this is enough to drive even a corner reflector to cover the distance we need. (It's barely enough to give a clean signal on the TV by direct coax connection!)

We have tried using a 2.4 GHz system, but we have several nearby WiFi systems here that it interferes with. We want to get completely away from the 2.4GHz range. My initial plan is to use UHF channel 14.

Thanks for the pointer to MiniCircuits. I've seen ads, but hadn't thought of them. I'll look into them.

Following are excerpts from FCC Part 15 regs (http://wireless.fcc.gov/rules.html) that I think would apply. Note that the allowable field strength is the same for both unintentional and intentional radiators in the frequency range of interest.

Subpart B_Unintentional Radiators

Sec. 15.109 Radiated emission limits.

(a) Except for Class A digital devices, the field strength of radiated emissions from unintentional radiators at a distance of 3 meters shall not exceed the following values:

[[Page 774]]

Field
strength
Frequency of emission (MHz) (microvolts/
meter)

30-88..... 100
88-216..... 150
216-960..... 200
Above 960..... 500

Subpart C_Intentional Radiators

Sec. 15.209 Radiated emission limits; general requirements.

(a) Except as provided elsewhere in this subpart, the emissions from an intentional radiator shall not exceed the field strength levels specified in the following table:

Measurement
Frequency (MHz) Field strength distance
(microvolts/meter) (meters)

0.009-0.490..... 2400/F(kHz) 300
0.490-1.705..... 24000/F(kHz) 30
1.705-30.0..... 30 30
30-88..... 100 ** 3
88-216..... 150 ** 3
216-960..... 200 ** 3
Above 960..... 500 3

** Except as provided in paragraph (g), fundamental emissions from intentional radiators operating under this section shall not be located in the frequency bands 54-72 MHz, 76-88 MHz, 174-216 MHz or 470-806 MHz. However, operation within these frequency bands is permItted under other sections of this part, e.g., Sec. Sec. 15.231 and 15.241.

Sec. 15.23 Home-built devices.

(a) Equipment authorization is not required for devices that are not marketed, are not constructed from a kit, and are built in quantities of five or less for personal use.
(b) It is recognized that the individual builder of home-built equipment may not possess the means to perform the measurements for determining compliance with the regulations. In this case, the builder is expected to employ good engineering practices to meet the specified technical standards to the greatest extent practicable. The provisions of Sec. 15.5 apply to this equipment.

Ever since you were 'outed' as a CBer, you've been engaged in this damage limitation exercise which, to be quite honest, smacks of effort. Nobody really gives a toss whether you own a CB-set or not...its your 'holier than thou' attitude which people find 'old'.

However, at least I *can* criticise you without fear of having my door smashed down by the police and being arrested for intimidating you. You can also be sure that, should you criticise me, which you are equally entitled to do, I will take it on the chin like a decent chap and not get all stroppy about it at the local lodge.

From: "Ivan Makarov" on Thurs, Dec 1 2005 11:47 pm

>Hi,
>does anybody know if coating on Amidon toroidal cores has any dielectric
>properties, such as a particular breakdown voltage rating, or it is not
>meant for electrical insulation.

Since Bill Amidon sold his business to another company, the "new"
Amidon company has been reselling another company's toroidal core
forms.

The original Amidon company resold Micrometals toroidal forms.*
Micrometals still very much in business in Anaheim, CA; website:

http://www.micrometals.com

Micrometals also makes power-application toroid forms for 60 Hz
and those are described as coated with Parylene C with a given
insulation rating of 500 V RMS at 60 Hz. By casual observation of
some Micrometals powdered iron toroid forms I have on-hand, the
coating appears to be the same. Parylene is a relatively inert
polymer which is unaffected by typical hydrocarbon solvents found
in varnishes and lacquers. I use McCloskey "Gym Seal" varnish
(oil based) as an over-coating of finished toroid windings with
great success in withstanding humidity and general aging. That
is available at most do-it-yourself hardware chain stores. The
same could be applied to the "standard" toroid forms if more
insulation of the core is desired.

The coatings on most toroidal cores is applied mainly to protect
the core material from oxidation. One can get uncoated cores
on special order but those unused cores should be sealed away
from air movement to avoid oxidation. The second reason for a
coating is to make winding easier and reduce sharp edges that
could stress the wires (true even with special toroid winding
machines)...especially if winding by hand.

There's not much need to worry about core insulation with
powdered iron materials. The powder itself is in a binder
which adds some isolation from breakdown in addition to holding
it all together. On actual application, check out one of the
early Amidon kits available in electronics stores, a 1 KW
Balun kit with huge core (to handle the RF power) and rather
ordinary coated solid wire. The RMS voltage at 1 KW in a
600 Ohm open-wire feedline application is 775 Volts. Given that
real-world antennas can get mismatched, high VSWR situations

could have double that voltage fairly easily. I've never heard of any such Amidon baluns that flashed-over in normal use (disregarding lightning strikes).

LenAnderson@ieee.org

* Micrometals has a minimum quantity requirement on orders, used to be minimum of 100 of any type core...that might have changed.

I didn't know that anyone else but Micrometals made powdered iron cores suitable for RF.

Amidon never manufactured their own cores. They used to carry Micrometals powdered iron and Fair-Rite ferrite cores, with a few other ferrite cores from Magnetics and other manufacturers. Whose cores are they selling now?

I want to build a hi current 12v supply, I know where i can buy a
6-12v 100amp battery
charger cheap. This charger had silenium (dont know the proper
spelling) rectifiers. Im
thinking the transformer must be alot higher voltage than a similar one
in a modern charger
using silicon diodes. If i know the drop than i can figure the
transformers output voltage.
So does anyone know the voltage drop of these old rectifiers?

5682. Re: voltage drop of a old silenium rectifier

Typically about 0.9v per section...when new.

The normal drop (at rated current) of selenium rectifiers is about 2
volts per plate.

Silicon rectifiers drop about 1 volt.

Schottky rectifiers drop about .6 volt.

After Bill posted .9 volts, I began to doubt my memory and looked it
up in a reference (Reference Data for Radio Engineers, 5th Addition).

A typical rating is 27 volts reverse per cell, 600 mA to 1950 mA per
square inch (that 100 amp supply must have a lot of square inches of
selenium) and with a capacitive or battery load, 1.6 volts drop at
rated average current. However, they have an essentially resistive
aspect from about .5 times rated current to 2.5 times rated current.
That is, the forward drop climbs linearly from about 1 volt at .4
times rated current to 3 volts at 2.5 times rated current.

>suitable for RF.

I have a few left-over Arnold Magnetics powdered-iron toroidal cores that were used by RCA Corporation back in the 70s. For the high end of HF for maximum Q.

Must have been a pot full of powdered iron core makers during WW2. I still have some screw-in "slugs" which were sold under "surplus" in 1948 at H & H Electronics in Rockford, IL. Their Qs peak at around the bottom of HF. The old AN/PRC-6 Handy-Talky of Korean War time had little powdered iron slugs for preset tuning...and it covered low VHF. Collins Radio used them quite a bit in the now-famous R-390 series of receivers (besides as permeability-tuned master oscillator).

I'd say that the ham magazine editors didn't get around to playing much with powdered-iron cores in the last half-century so not much was stated about them. Few hams had Q Meters at their disposal (way too expensive) and toroidal coil winding is a picky thing done by hand. Folks in the RF industry knew about them long ago.

>Amidon never manufactured their own cores. They used to carry
>Micrometals powdered iron and Fair-Rite ferrite cores, with a few other
>ferrite cores from Magnetics and other manufacturers. Whose cores are
>they selling now?

Bill Amidon set up a small packaging business as a sideline to working at NBC Western Hq in Burbank, CA, many years ago. He included data from Micrometals and Fair-Rite in those packages as they applied to the kit. Good deal for the average hobbyist. Micrometals turns out toroid cores almost like Krispy Kreme makes donuts in each shop...and they don't make real money selling in singles or very small quantities. A reseller/packager like Amidon could make some profit. It served the more serious home-builder very well, no minimum

quantities and rare Q curve info was included.

At www.amidoncorp.com you can find a line card on PDF as well as in HTML at that page. The PDF didn't want to download this night for me...:-) Amidon stocks/distributes Micrometals, Fair-Rite, Philips/Ferroxcube, Arnold, Ferronics, Chang Sung, American Cores & Electronics (located in China near Hong Kong), Associated Components, Coiltronics/Cooper, NEC/Tokin, Coilcraft, Mag-Layers, AEM, Magnetics Inc.

"Amidon Associates" (the old label for the plastic envelope kits) is now described as a custom winder of coils under the Amidon Corporation umbrella.

As to getting toroidal cores in small quantities, I found that www.partsandkits.com was quite good. Dieter Gentzow, W8DIZ, has that in Florida. Genuine Micrometals cores from what I could tell were in my order. Good prices, quick service.

A look at Arnold Magnetics' current catalog doesn't show anything suitable for HF or above(*). Do you know of any company other than Micrometals that currently sells powdered iron cores suitable for HF? I'd guess that while low frequency powdered irons are still pretty widely used in power supplies, the market for RF powdered iron cores must be relatively small.

(*) That is, materials having low loss at HF and therefore suitable for use as cores for inductors in tuned or relatively high-Q circuits. Like ferrites, powdered irons having high loss at HF can be very useful as broadband transformer cores, chokes, and in EMI suppression.

The only thing I think we have on here that's relevant is a spring
full of crocodile tears.

I can remember someone on here who went 'screaming' to 'the plods'
when someone wrote a letter to a family member; who made a complaint
to a university vice-chancellor because an employee sent an e-mail
three minutes after the end of his working day (and so must have
written it in 'works time'); and who approached someone's head teacher
regarding his appearance on here. Doubtless there were other
incidents. He also referred to people who belonged to a tear-or-wrist
organisation as 'noble'. It seems that what was good enough for him is
not too good for anyone else.

Perhaps his latest sock-puppet is a reference to the time he dropped a
ball by saying that a spring-dashpot system was a mechanical analogue
of a coil-capacitor system, because they both exhibit 'resonance'.

I think I was commenting on the arrogance seemingly displayed by the
choice of name.

Despite having thrown off my ball and chain, I retain some old contacts
- I emailed one recently (a guy who has a research interest in
psychopathology) and directed him to this NG with particular reference

to certain topics.

His response was "... interesting"

Read carefully ! This specifically forbids operation in the TV bands
except as provided for in paragraph (g) and other sections.

Paragraph (g) does not provide for operation in the UHF band. The only
other sections I spotted that do permit operation in this band are
15.231, which permits only low duty cycle periodic operation, and
15.242, which permits operation only for biomedical devices operating
inside health care facilities.

Hello guys,

I recently picked up an old vector network analyser in working order
but minus the 3 interconnects between it and the
transmission/reflection bridge. These are specified in the manual to
be exactly 24" long, 50 ohms and terminated by N-type plugs.
I've been told the length of these patch leads is quite critical to
getting accurate measurements with this VNA, but am at a loss to work
out why 24" is specified when the frequency range of this device is
4Mhz to 1300Mhz. If it were only capable of measuring at one fixed
frequency, I could understand the need for a specifically cut length
of some fraction of a wavelength.
Can anyone explain the relevance of 24" in this context?
Also, will *any* 50 ohm coax suffice for this purpose or has it got to
be something special?
Thanks,
P.

it is likely the 'real' requirement is that they be exactly the same length.
though there may be some maximum length because of attenuation at the top
end. there is also a possibility that they figure in some length of coax
and calibrate that into the system, though i would think that is less
likely.

At least a half dozen companies off-shore (to the USA). There's
probably three dozen (give or take) in the world that advertise
but their product lines vary according to which kind they are
able to sell.

>I'd guess that while low frequency powdered irons are still pretty
>widely used in power supplies, the market for RF powdered iron cores
>must be relatively small.

It's just a specialized area of electronic components that has
been around for at least seven decades. "Small" is a sometimes
a subjective thing...depending on one's collection of catalog
data...:-)

In 1950 I had a chance to visit two companies, one in my home
town of Rockford, IL, (Greenlee Tool Co. division of Greenlee
Inc), one a small BC-SW radio factory in a suburb of Stockholm,
Sweden where my uncle-in-law was boss and only engineer. The
radios used Philips IF cans which had powdered-iron "pot" cores
and excellent voice bandwidth, sharp skirt response, etc. Those
Philips cans weren't advertised at all in the popular press but
they were relatively cheap in large quantities. Of course,
Greenlee chassis punches had been widely advertised and much
talked about by home-brewers back then. The actual production
area for the Greenlee chassis punches (sold all over the USA)
was about the size of my home office (13' x 13')...and they
also made files in that same cubicle. From the ads one would
have thought they had thousands of square feet of production

space! :-) Advertising can be deceptive. <shrug>

Powdered-iron and ferrite material production is done in huge batches prior to molding (powdered) or sintering (ferrites). It is relatively cheap per end item to produce. The QC needed costs much more per unit item than many other components (such as axial-lead resistors) so the manufacturers want to sell that in large lots. The only ones buying large lots are the manufacturers...who plan ahead for large-run (thousands of units) production. [you know this, of course, Roy, I'm mentioning it for others]

Most production lines shun making their own toroidal inductors because they are time-consuming compared to axial or radial-lead inductors. That's a specialized area and it is generally cheaper for equipment makers to buy them from inductor-making specialist companies. For home-brewers making as many as a dozen toroidal inductors by hand for one project, it is quite easy to do with normal dexterity. Doing it for hundreds of equipment units in a factory run makes production costs go up since the number of toroids needed may be ten times that. So, despite the clear advantages of a toroid form and closeness of magnetic field that is natural to it, many designers opt for the cheaper solenoidal form inductors. Some get the idea that solenoidal forms are "better" and toroidal forms should be "avoided" which is contrary to what they do.

Getting into ferrites, the microwave area has long been a user of specialized GHz-range ferrites for isolators, phase-shifters, attenuators, dividers, etc., purchased in certain stock sizes and ground to fit necessary physical shape. The makers of those materials tended to keep advertising to the specialized micro-wave side of "radio." Those parts just wouldn't work for the HF spectrum.

>(*) That is, materials having low loss at HF and therefore suitable for
>use as cores for inductors in tuned or relatively high-Q circuits. Like
>ferrites, powdered irons having high loss at HF can be very useful as
>broadband transformer cores, chokes, and in EMI suppression.

Cable TV spread in North America has been a great boon to Asian component making and aiding consumers with low, low prices. A good example is the little balun in most TV receivers made for decades allowing 75 Ohm or 300 Ohm "antenna" connection. Cheap and works over nearly a decade of frequencies. The same with "splitters" and "line amplifiers" (for several TV sets). It is difficult to get ads from the component makers themselves but those are starting to appear in the industry trade press. With the explosion of PC-making came all kinds of relatively cheap EMI-suppression material and gadgets around cables and the like. Whatever their material is tends to be secondary if it works.

The search for the ultimate high-Q coils started around 1950, popular in the amateur radio press with the SSB "revolution" needing it for IF selectivity. Was a BIG thing then as I recall but that wound down as mechanical and quartz filters became available with their "textbook" filter responses. That led to a general feeling of "high Q is always better" for nearly every tuned circuit or low/high pass filter. Corners on bandpass filters HAD to be sharp according to "CW" (Conventional Wisdom). Not really so in practice. A few hours of experimentation on computers with CAE analysis modeling actual Q losses will show many misconceptions on the "necessity - always - of high Q." The same with "chokes" and even sharp tuned circuits for tubes (which need a high impedance tuned circuit for maximum gain).

To me, a toroidal form is superior for holding IN the magnetic field, thus enabling a toroid to be snugged down to a substrate with little effect on inductance or Q. That also allows toroids to be placed closer together with much less mutual interference. One just can't do that with solenoidal forms without individual inductor shielding. Philips has a couple of great application notes on broadband toroidal transformers and "how to do them" written back in the early 70s...reissued on their big website around Y2K. [links are buried in some archive CDs, not handy]

Please pardon a few "editorial comments" in here...it's a very quiet Saturday and I'm trying to procrastinate away from hitting the crowded stores for gifts. :-)

The phase shift due to the 24 inch coax cables are factored into the Network Analyzer for all frequencies and so any different lengths will cause the correction factor which is built into the analyzer to be wrong and that will make the reading displayed on the screen to be in error.

The phase velocity for most coax cables are similar, so I'd use RG-8 since that accepts type N connectors reasonably well. The impedance bump caused by a thinner cable being adapted to type N cables would be noticeable especially at higher frequencies.

The only major question is whether the original cables had a different velocity factor, and that I can't answer so I'd use the RG-8 and it should be close enough.

Hi folks,

I have a Telemobile radio which is labeled "FCC I.D. D4T9MP725"
(I cant find any reference on the FCC web data base)

Looking at the PCB it apears to be: 6 channel, 25 Watt, FM, VHF high band.

It uses a 2SC1946A PA and a 2SC2237 driver. The IF is a MC3357

I'd like to convert it to 2 Mtrs, but first I need a circuit diagram.

Can anybody help please?

Would be happy to pay any reasonable costs.

Tks ..... Zim VK3GJZ

Why not feed your signal into an MATV (Master Antenna TV) amplifier and route coaxes to the rooms where you want to hook up a TV? You wouldn't need 100 mW to do that....of course, you would have to run coax throughout the building and in old construction, it could be a pain...

5710. Ground resistance tester

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-04 20:43:47 UTC
From: AG4QC <Joel@cyberbest.com>
Message-ID: <dylkf.4473$lh.123001@news.sisna.com>
Source record: 15693

I was wondering if anyone built some sort of ground resistance tester? I read that the NEC requires 25 Ohms or less.. But I don't understand how to measure that. I certainly could use a ohm meter between a ground rod and the test subject, but then the ground rod I use as a reference could be faulty.. It seems to me it must be measured in some other manner. Maybe low frequency signal and then measure how much it's absorbed in the earth?.. I know they sell a clamp on ground resistance tester for big bucks. Considering it's a clamp on, it certainly don't have any external reference.. Anyway, I was wondering if anyone had any experience with these testers and maybe building one?

Ground resistance varies considerably with frequency, and at HF it can be very different from the DC or 60 Hz value. (For example, pure water is virtually lossless at DC and low frequency, but very lossy at HF.) And in order to get a decent representation of ground, you also have to know its dielectric constant. The only reasonably accurate method I know of to make these measurements is a system using a buried transmission line, called an OWL tester. I've never seen or used one, just read some papers where it was used.

If your need is for an NEC model, you should realize that the skin depth of current in soil in the HF range is on the order of 10 - 20 feet, meaning that significant current exists to well below this depth. Soil is seldom homogeneous, so to make an accurate representation of real soil, you'd have to test the soil at various depths down to perhaps 30 - 50 feet or so, then make up some sort of average value for the program to use. I don't believe any single average value will really be a good representation of a typical stratified ground.

So the bottom line is that even if you could accurately measure the surface soil conductivity, you wouldn't have enough information for an accurate model. And in fact, even if you could measure the conductivity and dielectric constant to a great depth, the model still wouldn't be very good because of its assumption that the soil is homogeneous.

About the best you can do with currently available software is to estimate the best and worst likely soil characteristics which might occur from the surface to a few tens of feet depth. Run simulations with both. The antenna performance will probably end up somewhere between the results of the two. Even that isn't guaranteed, though, since any single value probably isn't adequate to represent a stratified ground.

Ground modeling is the weak point of all NEC-type programs. Don't put too much weight on results which are strongly dependent on ground characteristics.

Did you also receive a calibration kit with the VNA? If you did so, then the lengths of these interconnect cables are not crucial for calibrated measurements. Only uncalibrated measurements will be affected.

It would help to know the manufacturer and model of the VNA.

Source record: 15698

Well, yes that's true.. In this case I was talking about the NEC (National Electrical Code).. Sort of a basic electrical question, from a ham radio prospective. They put up a Satellite Internet dish on my roof and it was too far away from the 'Service' protective ground so it's not grounded. So I ran my own bonding ground wire to tie it into the rest of my single point grounding system. It started me wondering just how affective all these ground rods were, even though they are all bonded together. So that started me looking around for a way to measure the resistance to ground, as I figure the less the better. Of course, in this case I am talking about 'protective' ground as required in the NEC handbook. The electricians around here eyes glaze over when I ask about the 25 ohm or less requirement.

So I figured maybe someone on here had experience measuring the required ground.. It would be my luck the house would take a minor lightning hit and the Insurance company would try to weasel out of there responsibilities by saying the ground didn't meet the NEC requirements not to mention I rather not have issues. While unlikely, I hear all sorts of horror stories on how they are trying to disallow claims for all sorts of reasons after Katrina.

Accuracy as in reading + or - 0.01 vs reading of 0.01 ohms absolute -
very big difference in technology involved. ;-) You have to define
what they are doing.

try the RF 2360 from RF microdevices.
it looks scary but with a little bit of patience you can hand make a
small PCB for it. except for thr input and the output oins, all others
are grounded. if you make you PCB out of a 31mils thick board, all you
have to do is scribble a pair of 50 mils wide line and a few
noncritical pads to anchor the power decoupling componnets. it's
specifically designed for CATV use, good from 5 to 1500 MHz.

> experience measuring the required ground..

Well, not a lot of experience, but the keywords you're looking for are "fall of potential".

Depending on which spec you're meeting, you drive multiple ground rods in at distances that are large compared to the length of the rods. Then you measure the resistance between the rods.

Just sticking your ohmmeter leads between two ground rods is not good enough. There is a substantial chunk of 60Hz AC and probably some DC current flowing in the ground and the little battery inside the ohmmeter will generally add nothing. Fall-of-potential meters use much larger currents (and usually measurement techniques, like using an AC frequency unrelated to 60Hz and harmonics) to overcome this.

My impression with antenna installations that I've been peripherally involved in is that NEC requirements (25 ohms) are generally easy to meet unless you've got dry rocky soil. And that the 25-ohm requriement is nowhere near good enough to protect your equipment/buildings from a direct hit.

Tim.

Source record: 15702

If a 60 Hz measurement is the only physical test that is available, that is better than nothing. The experts say that is useless, but I do not agree 100%.

Once upon a time I used a 12.6 V 60 Hz transformer and an AC ammeter to measure the current between some ham radio ground rods and the building utility ground and then calculated a resistance value of about 16 ohms. The substantial current flow helped to overcome an initial high value of resistance. The ground path did not seem to be perfectly linear at very low current values.

What the 2 to 30 MHz values were I have no idea. A high power (100 W) HF signal and an RF ammeter would have been a better approach. This test has to be carefully designed to reduce HF impedance effects.

The best approach, I believe, is to use an antenna design that does not utilize a ground path return impedance. In a balanced system the return current is through a transmission line, not the earth. A multi-wire ground plane with a transmission line return path is also a good approach that is very often used. Common-mode currents that try to return on the outside of the transmission line must be attenuated using a current balun.

It sounds to me like you are looking for legal advice, not technical advice.

With that in mind, and a lot of bad experience with lightning, I take the attitude that the NEC establishes the minimums for protection. After all, what can an extra ground hurt?

Last summer I had lightning rods installed on my house. I live on a low ridge and have taken several (expensive) hits over the last few years. They installed ground rods on two corners of the house and tied one of them to the service ground. They also tied the Antenna tower to the opposite ground rod. I added another ground (#6 wire) from the Cable TV ground rod to the service ground. I also tied the Cable TV ground to the ground rod on the invisible fence (dog containment) with #6 wire.

With all of that I still don't have a good RF ground. I hope to put up a vertical antenna soon and the first thing I need to do is establish a system of radials. Of course, the first wire will be a #6 to the service ground.

BTW, I don't understand "too far away from the service ground to be connected."

It's an inductor? ;-)

No such thing as a capacitor, or an inductor
or resistor for that matter. They all have
to be modelled as networks with L C and R
don't they?

I think others have touched on the key requirement of testing at least
three grounds rods. Then
from the three (or more) readings you can determine each resistance
value. As others have pointed out
you probably need a high current to mask the other currents in the soil.

Cheers.

Worked much DX with Spice, have you?

IMHO if the results from spice differ from the
real results then spice is wrong.

BTW have you got a realistic model for the
self-capacitance of an inductor? Can you
predict the self resonance within 5%?

Try them on a toroidal inductor, even at HF. I have good reason to
believe they won't have anything like a model to predict self
capacitance/resonance.

Model making is driven by need. 1nF capacitors don't exist on-chip
(at least not very often :), so I don't have a model. But I have
built a model of a wirebond that is good up into the 3GHz range.

Please ignore my earlier posting. I saw NEC and thought the reference was to the program of that name (Numerical Electromagnetics Code). The other responses caused me to re-read your posting more carefully and I see you're referring instead to the National Electrical Code. 60 Hz measurement is of course what you want to do, and my response was entirely inappropriate in that context.

Sure Jim. I understand you. That was the time where time was cheaper. Once I programmed a Gauss linear equations system solver on my Casio FX-602P - having 512 bytes and even left one byte (for extensions ;-) It was with minimal input help system (Showing the indices to input) and the matrix was of dynamical order. (Sorry for my bad english)

I can buy resistors and capacitors with 5%, sometimes with 1%. If you build a rc oscillator with 1% component values, you get an error typical 1,5%. And then you add the active components with horrible semiconductor strayung values. Of course, it is possible with feedback structures to linearize and stabilize such systems.
So, where is the difference between measurement of the component values and calculating by hand the circuit OR setting the measured values in the Spice component dialog boxes? The difference is the time needed and the possibility to make errors.

5% is a real good value for an analog system.

Hey Jim - Why you don't answer my second private message? :-(

- Henry

5738. broadband transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-06 16:17:20 UTC
From: gojamo <gojamo@peoplepc.com>
Message-ID: <1133885840.604319.174600@g47g2000cwa.googlegroups.com>
Source record: 15721

Can you connect a broadband rf transformer to a receiver front end tank circuit rather than to a resistive load? The inductance of the side of the transformer connected to the tank circuit would be several times the inductance in the tank circuit, and changes to the overall inductance (parallelled inductances) of the circuit would be taken into account. Thanks

5739. Re: broadband transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-06 17:06:42 UTC
From: Leon <leon_heller@hotmail.com>

Source record: 15722

It would have to be matched to it, of course. Combiners based on
broadband transformers are often used to feed receiver inputs, when
testing front-ends for intermodulation and so on.

Leon

5740. Re: MESA Quartz Crystals

A crystal running in 7th overtone mode has a narrow little resonance
surrounded by other resonances (the 9th and 5th) which must be filtered out.

A crystal running in fundamental mode has a pronounced resonance, with
no other significant resonances until you get to three times the
operating frequency.

If there's anything "wrong" with that circuit it's most likely that the
frequency selective elements to keep it from jumping to 89 or 161MHz.
It may also deliver more feedback to the crystal than absolutely
necessary (dunno about that). So if anything is bad about it it's just
that it has too many components.

It's probably a very good place to start, and should work as-is if you
get the tank tuned right.

Yes.

The inductance of the side of
> the transformer connected to the tank circuit would be several times
> the inductance in the tank circuit, and changes to the overall
> inductance (parallelled inductances) of the circuit would be taken
> into account.

You can often make a better broadband transformer by using low-frequency, high-permeability ferrite for core material than by using higher-frequency, lower-permeability ferrite. This results in a winding impedance that's high, but primarily resistive through the HF range and above. The advantages are that a high winding impedance is relatively easy to achieve, and it stays quite constant over a very wide frequency range -- typically several decades -- since it's free of resonant effects. What you have to insure, then, is that the winding impedance is at least several times higher than the impedance seen by the circuit it's across. If it is, the fact that it's resistive rather than inductive is of no consequence as far as the external circuit is concerned.

You could use one of three mostar programming options... the Epson
Suitcase programmer (yuck... I hated using it), the Motorola R1800
suitcase programmer with the proper firmware installed or you'd receive
the proms from motorola direct.

We used to get the whisker problem all the time. A good blast of air in
the rx preselector would pretty much fix it.

The VCO Coil fix was a replacement retrofit coil Motorola would sell
pretty cheap. Never had the problem after that...

All things considered, they were pretty good radios really. If you had to
play with one now... I'd probaby remove the prom and replace it with an
eprom module I've seen offered for the MCX100 radio. You'd need to map the
prom into the eprom map, but it wouldn't be rocket science.

cheers,
skipp

Hi Steven,

Please read the Swan and Siltronix Radio "care and feeding"
information found on my Swan and Siltronix Radio web page.

www.radiowrench.com/siltronix

The drift fix should start off with a good cleaning and
conditioning using the information I describe in the pages.

Don't crack open the vfo box until you've read my information
and asked a few more people for help.

The radio probably hasn't run in a while... it might need
new filter caps in various places. The contacts all need to
be cleaned really well and restored using the proper chemicals
and lubricants.

The unit probably has a lot of moisture build up. When I
rebuild radios... a temp cycle and moisture bake out are
always part of the process.

Email me through the web page or through the yahoo groups
I frequent if you have more questions. You really don't
need the added vfo box mods if you're patient with the proper
rebuild.

cheers,
skipp

Whew, thanks, Roy, I thought you'd finally "lost" it! (hi hi and grin)
I wish I had something more solid to contribute, but I do remember my USAF days when the aircraft parking ramp static grounding rings required a scheduled resistance inspection, the date stenciled in black on yellow circle. The resistance had to be below 10,000 ohms. The instrument the civil engineers used to make the measurements was hand cranked, something like the "Megger" used for insulation break-down testing. I cannot say whether it was a regular "megger" or a specialized instrument.
Anyhow, we mechanics tried to do our own testing with an ordinary VOM and found the task quite vexing. One problem was that stray currents in the ground drove the ohmmeter crazy, and as if that wasn't enough, the ohmmeter probes current caused an electrolytic (?) reaction, sort of like trying to measure the resistance of a battery using a standard VOM.
Now I'm going to back up and read some of the references provided by previous responders.

...sure you can. I think you noticed that sometimes the antenna is
connected to a tap on the inductor, thus creating an autotransformer.
The one thing to beware of is to make sure that the input impedance,
reflected through the transformer is high enough, so as not to load the
tuned circuit. it's NOT a match. If matched, the impedance of the
transformer's secondary would be equal to the tuned circuit's
impedance, thus lowering the Q of the tuned circuit to one half the
original value.

If they specify a physical length (24"), and nothing else will do, then the type of coax is absolutely critical as its velocity factor will determine the electrical length.

However I suspect the bridge output is not at signal frequency but DC so the cables will not be critical. It is very difficult to see how they could make it work to 4GHz with several wavelengths of coax in the signal path, acting as an impedance transformer. Two feet is a significant length even at HF, and will shift the phases considerably.

Speaking of electrolytic reactions....
I would try a tool from the tv service industry called an ESR meter.
It measures the internal resistance of electrolytic capacitors by
using an ac signal of moderate frequency around 100K Hz. They can
typically measure from 0.09 ohms to 199 ohms.

While most tube rigs will drift *some*, I found that turning on my Swan 700CX about 30-45 minutes before using it did a LOT to reduce drift. I think, too, that newer hams, not being familiar with the old tube rigs, are more critical than those of us who are familiar with them. I hear people putting down Swans ("I HATE them old Swans cuz they drift"), but it isn't all *that* bad! :) I mean, just think, what did we DO back in the glowing tube days, right? If it had been THAT bad, we'd not been able to function. Sure---Swans drift and have a reputation for it, but I owned 3 of them and never had THAT much trouble. I HAVE had worse!

Do you know what load they are cut for? That osc is for overtone operation
and those usually run the crystal in series mode.

Start using Google more... This may be just what you need.

http://www.sss-mag.com/pdf/saosc.pdf
I'm not familiar with MESA's, but If this is the crystal type, this may
help.
It is just for MESA resonators and appears to say they are series cut. It
also looks like a good general reference on crystal characteristics as it
shows the typical resonances at the overtones.

http://www.icmfg.com/crystaloscillatordata.html
If I thought they were parallel load xtals, I'd start with the fundamental
Colpitts if they are parallel crystals, but a tuned circuit may help to
improve the phase noise.

Look at is when the receiver input is tuned. The receiver input will look
resistive (for example 50 ohms). The transformer is therefore loaded by a
resistive load (as it should).

Thanks Saandy! I knew CEL but forget them ;-)

Seems the NE85633 is really cheap and good performance. The package is
reasoable for hobbyists.
Do you already converted the parameters to spice and is it possible to
provide the file to me? Thank you!

Should be a good oscillator and all-purpose amp...

Sure, plain wire is better than the manufactured coils if possible to apply.

I have a nice line of 2% caps in stock, but where do you
get the elusive (affordable) 1% capacitors?

Saandy,
I respectfully disagree, in part. I believe you want to re-think this.
I know it "looks like" you are just paralleling two inductors, but the whole thing must be considered.

There is such a thing as loaded Q which is what you will see when all is connected up. When un-connected, you have an "un-loaded Q" situation...and they are indeed different. The loaded Q is a very important and specific consideration when designing filters. The loading of the external circuitry (and resulting loaded Q) has to be taken into account when designing for a required bandwidth.
Also, there can be a match, and should be for sensitivity, aka maximum power transfer. Well done, the receiver input tuned circuit will appear resistive or nearly so. The tuned circuit(s) provide impedance matching between the antenna input (50 ohms) and the first device (usually higher Z), as well as filtering -- two functions for the price of one.
Side-bar: When considering noise figure, there can be a different ball game, but it is a relatively small difference - impedance wise.
A well designed RF transformer will reflect (look like) 50 ohms at its output (receiver input) due to the (supposedly) 50 ohm antenna/feed-line connected to its input (antenna side).

Obviously I am assuming a 50 ohm system, to explain.

A tap is a way of impedance matching and the auto-transformer analogy is a good way to look at it. I call this a "Mental Model" for better understanding what is going on - it works to analyze things. Because 50 ohms is a relatively low value, tapping a coil is a way to get to a lower impedance from the relatively high impedance at the top of the coil/tuned circuit. Capacitive tap is another common way (they just have differing secondary [side] effects in far-out attenuation).

Comments?

Anytime you buy something worth a pretty penny at a hamfest, get the seller's callsign and contact phone number. Don't know how many times I've had to contact hamfest sellers after the sale about broken items that were well advertised as "working perfectly". Many times you come across some insane deals, but you'd be surprised how much lying and deception occurs at hamfests especially with stuff that works, but has tons of little problems you don't realize until after you get home.

You asked this same question, about what I assume is this same radio,
back in January of this year. There was a whole thread of discussion,
which lasted over a month.

The thread seems to have ended up with pretty much everybody
concluding that you'd have to send the radio back to the manufacturer
for repair, if you want it to work properly.

I think that's still your best choice. Asking the same questions over
and over again, and expecting people to be able to diagnose an
intermittent problem at a distance, seems unlikely to help matters.

Yup, buy it at scrap price and if it works when you get it home, you made out! What happened to the old days when hams would tell you this and that didn't work? I suspect it was about the same time that radio gear went to microproccesor control and things got to tiny for hams to see, let alone WORK on it! There's not too many Heathkits that an average ham couldn't fix, but nowadays it takes an engineer, a technician, a magifying glass, a tweezers and a cold to work on anything (the cold is so you can sneeze while unsoldering components and blow them off the board and out of the radio. Just worked on my Yaesu 857 tonight to modify for full coverage transmit to use with my transverters. They use jumpers that are about the size of a large piece of pepper...

Are you joking?

If not, the best looking would be if you hide the antenna in the fender wells or under the truck.

Most of us are more concerned with the best performance, which likely will be on top of the cab.

Harry C.

OR two capacitors in parallel. The support cap has a nominal value of 1/100
of the bigger cap. So you can tune the bigger.

Digikey stocks a handful of Panasonic ECQ-P(Z),
POLYPROPYLENE, Radial, 0.001 to 0.47 uF.

Not a great selection, but probably good enough for
many timing applications if you do the fine tuning with
the size of the R.

That's good to hear of, thanks! The 2% parts I have in stock
are the same series, but cheaper 2% parts. I didn't realize
DigiKey carried so many 1% film capacitor values in stock.

For timing purposes I suggest using a ready-to-use clock generator in tiny
SOT-23 or alike. For example from www.linear.com and www.maxim-ic.com
They have a accuracy well in the 2% range and can be tuned with a little
resistor 1%. Maxim sells a 32768Hz variant - crystal controlled.
They're all digital ouput!

Building a 32KHz oscillator with a clock crystal and having sinus output is
really simple with CMOS buffers.
You can mix the signal with RF getting an IF somewhere. Look at the app note
at www.cypress.com how to build a time-code receiver using that concept -
just of the cystral and cypress mixed-signal controller.

5783. Reading data back from HP4195A

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-09 15:57:17 UTC
From: Larry Martell <natkelcri@yahoo.com>
Message-ID: <1134143837.339943.191660@g49g2000cwa.googlegroups.com>
Source record: 15616

I am writing a program to control a 4195 over the HP-IB bus,
and I can't seem to find the command to return the data from
a sweep. I have worked with many other HP test instruments,
and usually there is a command that sends back the entire data
set after a sweep is completed (e.g. on the 3562A that command
is "DDAS"). Anyone know would I get the sweep data back from
the 4195A?

TIA!
-larry

5784. Re: MESA Quartz Crystals

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-09 16:25:14 UTC
From: Steve Nosko <suteuve.nosukowicuz@moutouroula.com>
Message-ID: <dncb5a$2er$1@engnntp2.cig.mot.com>
Source record: 15618

OK Rocco,
Now that I read the paper (URL below) on MESA crystals, I can comment better. They are nothing more than very thin AT crystals (in the center of a larger, thicker blank) and therefore have the normal AT cut characteristics.
The reference you give below is a general datasheet from the manufacturer. However, when crystals are manufactured they are made to a specific requirement with regard to what is called "load". This would have been at the request of the Engineer ordering the crystals. As explained in the paper I referenced, crystals can be used either in a parallel resonance mode or a series resonance mode.

Any crystal can be operated in either mode (any crystal can also be operated in one of its overtone modes - I have done this), but to get the frequency that it was manufactured for (and marked) you have to operate it in the mode it was made for. Therefore, if you expect to get the frequency on the crystal, you have to operate it in the correct mode. Just looking at the crystal, you can not tell for which mode or load capacitance it was made.

If you put a crystal in an oscillator which runs the crystal in series mode and the frequency is too low, then it was made for parallel operation and needs a parallel type circuit like the Collpits. If a crystal is put into a parallel mode circuit and it can't be brought down to the marked frequency, then it is a series mode crystal. If I recall, the Pierce operates the crystal in series mode. For reference, if I recall the difference between the parallel mode frequency and series mode frequency is around 200-300 ppm. for fundamental crystals in the 1-30 MHz range.

For lower frequency crystals it is common to specify in the range of 20-32 Pf load for parallel mode operation. There is no analogous "value" for a series operated crystal...just saying "series" is enough.

Another consideration not mentioned in the overview paper that I reference is that of power dissipation. Putting too much energy into the crystal will heat the material and cause frequency drift. Though not discussed, I can only speculate that the MESA construction requires a lower power operation than non MESA because of the thin blank.

5785. electronics/rf coursework for hobbyist

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-09 16:50:34 UTC
From: Matt <mthomas@biocontrolsys.com>
Message-ID: <dnccl2gie1@domitilla.aioe.org>

Greetings,

I'm a relatively new ham with not much in the way of electronics knowledge who wants to be able to build and understand my equipment. I recently enrolled in an electronics program at the community college to try to change that. Unfortunately, there are no rf/antenna/wireless related courses (sadly the wireless program was cancelled last year). What kinds of general electronics classes (or other type) will best help me understand radio electronics? This quarter I took DC circuits. Next quarter will be solid state. I'll take an AC principles course later. While the local university has electrical engineering courses, they don't teach them at night, so I'm limited to what the community colleges can offer.

Thanks,
Matt

It sounds like you're on the right track. If you can take a semiconductor devices course at the right time that'd be good, but they're usually 3rd-year courses & may not be taught at community college.

You should have a copy of the ARRL Handbook. The 2004 copy that I have does a pretty good job of presenting all of this stuff. From my perspective as a practicing EE it's a bit watered down, but the information is quite accurate as far as it goes and it's certainly adequate for a lot of design tasks. The handbook is a book that you can reasonably expect to see on the shelves of any EE active in RF design, and you can expect that it'll get referred to from time to time.

Going beyond the handbook Hayward's "Radio Frequency Design" is a good book to read after you get through the AC principals course. I have it and I like it, but it is written assuming you have quite a bit of EE coursework under your belt. If you can't take a devices course you'll either have to spend lots of quality time with the ARRL handbook or get a text from a devices course and ask lots of questions. I hear "Experimental Methods in RF Design" recommended here, although I don't have a copy myself.

If you really get serious about the handbook you should try getting one copy per decade going back to the 70's. Their opinion of what's "useful" changes from time to time, so it's not just the same book over and over again. If you go nuts about the handbook you should get one

copy per year, perhaps two or three (one for display behind glass, one to read in the living room, one for the shop...). I'm up to 9 copies, including the '76 copy from when I got interested and my uncle's '45 copy that I found in my grandmother's attic. I find I have a terrible fascination with the circuits in the '33 handbook with those open-air tank coils with 2kV on them -- and capacitors located so you have to reach over the coils to adjust them. It puts the term "electrical safety" into a very interesting perspective.

Thanks for the advice, Tim. It looks like the solid state class might be the same as your semiconductor devices course? From the course description: "Analyzes characteristics of semiconductor devices and their application in common electronic circuits. Covers construction of simple power supplies and more complex amplifier circuits and regulators. Includes construction and measurement of devices and circuit parameters to verify math analysis of circuits designed." There are also classes in analog circuits and devices and in digital circuits.

Thanks,
Matt

That sounds like a match. Of course I can't answer for the quality of
the coursework compared to a Uni, but then it depends on which CC and
which Uni.

5789. A Frequently Asked Question (FAQ) (At least, by me, for the benefit of novices)

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-09 18:43:37 UTC
From: Pierian Spring <aiyr.r.bean@lycos.co.uk>
Message-ID: <1134153817.613209.156800@g49g2000cwa.googlegroups.com>
Source record: 15622

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured

the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an

apology for the failure of a CBer are those class B licensees who falsely proclaimed that they were against the use of a Morse Test to control access to the HF bands, until, that is, a test was introduced at their intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to enable them to handle even the simplest algebraic manipulation for Ohm's Law and thus, the disgraceful Class Ber's in the aforementioned category are not Radio Hams by any stretch of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds, or has ever held, a licence issued under the gangrenous degeneration that is the M3/CB Fools' Licence scheme!

This one *may* be harder without the AC class under your belt.

Also talk to the instructors. They may suggest books or even give / lend
you something. Also ask about hams in the area.

It has its own abiding fascination for some of us. And if you get
selfish idiots on SSB encroaching on the CW end of bands, you can blow
them away without difficulty and still carry on an uninterrupted QSO
with fellow CWers.

Then that's fine for you and your CW friends but is it really the top goal
all Amateurs set out to achieve... to go dah dah dah dit dit dit dah dah
dah? Don't you also enjoy talking to distance stations with your voice too?
I agree that the part of the spectrum allocated to Morse should be left for
Morse and those who wish to use Morse should have a slightly different level
of licence/callsign to acknowledge this but it seems its always but "always"
levelled at us with any discussion about seemingly low licensed
intermediates/M3's/general class that unless your an extra class/advanced
you are some sort of trailer park scum. Not for one minute am I saying you
say this but its the general impression most get from some "alleged" full
licence holders in these newsgroups.

Regards and Happy Christmas,
Graham

<snippety>

Knowing the basics never hurts. My own electronics courses were generalized rather than aimed at radio, but I still learned a goodly amount from them.

Others have already pointed you in the same directions I would. My only other suggestion would be to, as your time and level of income allows, build up your workbench/lab with the best tools and equipment you can possibly afford.

Along those lines -- Learn how to take full advantage of the scrounging resources offered by ham radio swap meets (join a local club that does one a year, if possible) and electronic surplus stores. At the risk of shameless self-promotion, I have sections of my web site dedicated to such efforts.

http://www.bluefeathertech.com/technoid/swapindex.html

Some of your first investments, tool-wise, should include the basics -- screwdrivers in the flat, phillips, allen, and Torx varieties, diagonal cutters, both regular and flush, pliers, small wrenches (an ignition wrench set is very helpful).

I tend to avoid imported tools, with a few notable exceptions. I've found that the long-term quality just isn't there, notably in the junk we get from China and Taiwan. Buying US-made stuff is a bit pricier, but it's a far better long-term investment.

Some of the names I go for are: Bondhus (Allen wrenches), Wiha (regular and Torx screwdrivers, west German import, great stuff!), Cooper Tools (US-based, formerly known as Xcelite) and, for power tools such as drills, saws, etc., DeWalt.

As for test gear, I could probably write a book. At the very least, you're going to need a good multimeter (Fluke 87 series is my

personal favorite), probably a small bench power supply (or a large one, if you plan to run mobile gear on said bench).

As your skill level grows, you will likely find that you need more sophisticated stuff: Oscilloscope, signal generator, modulation analyzer, spectrum analyzer, LC meter, etc.

I could write a book on picking some of those, especially O-scopes. For now, suffice to say that you can get an awfully good 'scope for the $$ by going for older Tektronix equipment. Some favorites of mine are the 7000 series (7603, 7704, 7904, 7104) and their associated plug-ins for lab use. For portable (well, luggable anyway) use, have a look at the 465, 475, 485, 224x series, or the 246x series.

One excellent source of Tektronix information is the TekScopes group on Yahoo. I've been a member for years.

You're off to a wonderful start on a fascinating hobby. Oh, you'll hit bumps along the road -- we all do -- but keep up your interest in tinkering and you'll never lack for a learning experience.

Happy tweaking.

Hi I am using a HP8592B to do RF measurements and the marker, after a passed auto calibration, could be out 100 or 150 khz when measuring signals over the 300Mhz range.

This spectrum analiser is a non synthetised VCO type, and I don't quite know what frecuency measurement precision can be expected from it.

- Any experience on the marker frecuency precision on that type of spectrum analiser?

A link to the manual will be apperciated.

Tks in advance

Looking in a 1991 HP catalog, I see that you can expect a readout accuracy
of no better than 0.01% of center freqency + 2% of freqency span + 5 x N MHz
(this appears to be a term for the timebase accuracy). Keep in mind that
many spectrum analyzers are not precision measurement instruments.

Rigth, I have seen that info, (0.01% of center freqency + 2% of freqency span + 5 x N MHz), but I quite don't understand it ...

If say I am measuring a 300 Mhz signal, and I have a span of say 500 Khz..

- What is the precision or error that I can expect ?

Any hands on experience with that spectrum analizer, and in special regarding frecuency marker precision, will be welcomed.

> Any hands on experience with that spectrum analizer, and in special
> regarding frecuency marker precision, will be welcomed.

I haven't used that particular spectrum analyzer, but I've used similar
ones.
Let's deal with the first two terms:

0.01% of center frequency (300 MHz x .0001 = 30 KHz)
+ 5% of frequency span (500 KHz x .05 = 25 KHz)
= 55 KHz

Note: The catalog states that spans <10 MHz have 5% accuracy, not 2%.

This means that the readout may be 55 KHz off and still be within
tolerances. Added to this is the term: 5 x N MHz. What this is isn't
explained in the catalog, but there are other things which affect the
accuracy which may be included in this term. i.e.:
timebase accuracy/stability, readout precision and method of digitization.
Timebase accuracy (0.007%) and digitization (span/intervals) are probably
included in the first two terms. The last term might be concerned with the
frequency displays. Marker readout precision is a function of the number of
significant digits in the display. The display is essentially a frequency
counter and they typically are affected by the time base and have an
uncertainty of +/- one on the least significant digit. i.e.:
If the display shows 300, it may be 299 to 301. (3.33% error)
If the display shows 300.0, it may be 299.9 to 300.1. (0.333% error)
If the display shows 300.00, it may be 299.99 to 300.01. (0.0333% error)
... and so on.

Hope this helps, I'm not sure I can do more to help.

5807. Linear amplifier chain choices

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-12 09:30:54 UTC
From: kennnick@gmail.com
Message-ID: <1134379854.649360.281900@o13g2000cwo.googlegroups.com>
Source record: 15640

I'm doing my first SSB homebrew project and am learning a lot as I go. It's for 60 meters.

I've done the speech amp, DBM, crystal filter, transmit mixer, and one stage of post mixer amplification. This has taken me to about +6 dBm, and I want to get to +30 dBm. (I've already built a 1 watt in / 10 watt out "final" amplifier.)

My question has mostly to do with the number of stages and operating class. As I approach 1 watt, class A gets pretty impractical due to device dissipation, or so it seems. But I want to carry waveform faithfulness as far as possible. Is it accurate to say that if a class that doesn't give full swing in both directions is used, a harmonic filter should be used before the next stage? I'm trying to infer from what I see in the literature. I'm generally seeing a single device (not push pull) in AB (I think) just before the output filter, but not often at the lower levels.

I guess a push-pull stage could be used to give waveform linearity to get to the 1 watt level. I just don't know if that's needless complexity(?)

The next decision is whether to go from +6 to +30 dBm in one stage or not. I'm inclined to think 14 dB in one stage followed by 10 dB in the next would be best. Any guidance?

Source record: 15643

Hi Gang,
I have an old Oak Hills Research Classic 40/20 meter xcvr. I'm not sure if this is a new problem or something that has always plagued it, but I am getting several spurious signals on both 40 and 20. I have identified one of them as a local AMBC station at 1500KHz. After reviewing the schematic, it looks like the trouble could be in one of several areas. This unit makes wide use of diode switching for the Tx and Rx paths, and I'm suspecting the 50KW BC station is driving one of more of them into conduction.
The other possible culprit I see is that this rig has an untuned broadband BJT amp right after the LPF. This circuit is obviously biased at a fairly high level of current which I'm sure was intended to make it robust in the presence of >strong< signals, but I'm thinking it may not be able to handle all the RF it is seeing.
Before I tear into the rig and try some things, bypassing diode switching and/or adding a preselector to that RF amp, I wanted to check with you guys and see if someone has already 'invented this wheel'.

Tnx!

Bob WB0POQ

Depends on metal. A ferrous metal (like iron) WILL distort field lines.
A non ferrous conductor like copper or aluminum will not affect a
STEADY or DC magnetic field, but because of induction WILL effect an AC
magnetic field.

Curiously, however, it will affect the field in the opposite direction
to the effect of a ferrous metal.

Metals get involved with magnetic fields in two possible ways. All metals (and anything else with a finite conductivity) circulate current as any magnetic field passing through it changes strength. The circulating current creates a mirror image magnetic field that partially cancels the one trying to penetrate the metal. For any non superconducting metal, this process also consumes energy from the field. These circulating currents are referred to as eddy currents.

Ferromagnetic metals (ones that are attracted to a magnet) also have another effect. They act as a short cut for any magnetic field that lasts long enough for the above effect to fade out, at least for field strengths below their saturation limit. In other words, it takes more work to create a given flux in air than it does to create the same flux through iron. Since any effect that causes the total amount of flux to increase, generates a force in the direction of motion that allows the increase, this short cut effect is what causes iron to be attracted to a magnet. The work the magnet can do in attracting the iron is the work it took to build the field in air minus the lesser work it takes to build that field through iron.

Things get more complicated for electromagnetic waves. Both the electric field and magnetic field components of waves move surface charges around as they pass by or reflect off of conductors. Maxwell's equations are the most compact description that covers all these possibilities.

That's enough hand waving for now. My arms are tired. ;-)

Yes.

> How metal works with electric field,

If you ask what is the effect of a conductor on a magnetic field,
then: Because metal conducts, it tends to block, divert, change the electric
field.

> magnetic field,

A changing magnetic field induces current in a conductor which in
turn causes a magnetic field that opposes the original magnetic field. This
new magnetic field sums with the original to form a completely new magnetic
field.

> electromagnetic field?

Currents are induced in the conductor which sum to arrive at a
completely new electromagnetic field around the conductor.

> Thanks,
> SP

N is the 1st LO harmonic used for the front-end conversion. It is
always 1 for any frequency in the first band of coverage, so the
tolerance at 300 MHz would be +/- 5.055 MHz.

Hi Paul,
you can - but not recommended. Valves generate a lot of heat, and PCB
is not good at dissipating it - would have problems very soon. Why not
use aluminium sheet - easy to work as PCB, - I get mine form a local
scrap merchant, they have pieces big enuff to build any chassis I want,
and its a lot stronger AND cheaper than pcb.

Of course you can use (preferably double sided) PCB , also for
enclosures .

Good luck with your project

Hi,

I get a lot of broken TV's for scrapping from time to time, and it seems that just getting
rid of the tube in the trash is a shameful waste. But I do know that these are about the
only remaining vaccum tubes still in manufacture in this country. I understand that most
of the power is supposed to go through the electron gun of the tube, but I wonder if the
electron gun could be reconfigured as a linear final? Bad idea?

Sure.

> I don't see those big errors of 5 Mhz.

If the analyzer doesn't have a stabilization feature, and its frequency
accuracy is that good, it is pure luck. Don't count on it being that
close at any other frequency, or remaining that close at 300 MHz for
very long.

> Any pointers to the user manualfor that unit ?

Try www.manualsplus.com for a hardcopy, or if a search at agilent.com
doesn't turn anything up, ftp://ftp.agilent.com/pub/manuals/ .

...while others say "Go ahead".

For this application I'd agree with Andrew - the PC board is going to get HOT! I discovered this a long time ago, with a little VHF transverter that created much less than a tenth of the heat that a 300-400W PA will. Until then, I'd never appreciated how much we rely on an ordinary aluminium chassis to dissipate heat from the valve bases, or how well it does it.

Unless you use a blower is actively aiming to cool the board as well as the valves, the fibreglass is going to stew, turn brown and warp.

>Why not
>use aluminium sheet - easy to work as PCB, - I get mine form a local

That's basically true, but it just takes longer, and I don't suppose Paul will have all the metalworking tools we OFs have collected over the years. The main point is to make sure you get *soft* aluminium, and also try to get it cut to size. Or try to find some old radio gear that was built with a chassis and cabinet, and rebuild inside that... another honourable tradition.

There was once an SP station who soldered the bases of *ten* 807s on a sheet of PC board for his HF amp. But that was in another century, in a desperate country before the Wall came down. It can be done, but it isn't a good example to follow.

I would humbly disagree with this - aluminium is fairly easy to work. A metal cutting blade in your jigsaw, a set of drill bits, hole cutting saws are now very cheap (you dont need super HSS ones for soft aluminium, a rat tail file .. pretty basic tools...the stuff you need to work PCB into shape!

bending is a problem, I must admit - one day, will make a sheet metal bender - in the meantime, bits of angle iron clamped in a vise give reasonable results......

More fundamentally - why use PL519's - arent they TV sweep tubes, like 6JS6's - a poor choice in this day and age, unless you have a box of them cheap (plus the sockets...) Proper transmitting tubes are available at a reasonable price - even the humble old ones like 811A's would be a better choice!

....so, first of all a class A amplifier would dissipate aproximately
1W which isn't so bad. any TO-5 transistor with a clip on heatsink will
take that. A 2N5109 would be ideal, being a quite rugged device. you
don't have to worry.
second, about 12-13 dB of gain in the HF range would be an approximate
maiximum for easy and comfortable construction. higher gains are
possible, but you start to endanger yourself with oscillations. better
a 2 stage amplifier, even though it sounds more expensive. it's only
one of a kind so cost shouldn't be a main concern.

==========

Program COAXTUNE calculates Q when the line is tuned to resonance by a capacitor across the open end. For practical purposes this is the same as Q when off-resonance at the same frequency.

Open-circuit and-short circuit stub lines have the same Q.

As a check on dimensions of the inner and outer conductors the program calculates line impedance Zo. If you are uncertain of dimensions then vary them to make Zo equal to what particular type of line you have in mind.

The velocity factor of solid polyethylene coax is 0.665

The program allows physical line length to be adjusted for resonance at any frequency, and for any length in wavelengths.

At HF, for typical types and sizes of coax, you will find Q to be very much lower than 200 or 300. High values of Q are obtainable only at UHF and above on large diameter lines.

Download program COAXTUNE from website below. It is very simple to use.

Program TWINTUNE does similar things with balanced pair lines.

For design of a complete impedance matching system using a stub-line, coax or balanced-twin, between main line and antenna, program STUMATCH may be of interest.

the uncomplicate answer is "depends on the COAX losses which is
related to inner conductor diameter and insulator used".

Example RG58 is a poorer than UT141 but 1" Hardline will be better.

Tools like coaxtune and others will get you a better ide of what will
achieve your specific goals.

I doubt that he would get more than a couple watts out of a CRT, even
if it has 30 KV on the second anode. The ICs used to drive a computer
monitor's CRT, on the other hand? Some will work on two meters, and
higher frequencies and can be found in dead monitors all over the place.

I'm sure Reg's programs will give you a very good estimate. For a quick "rule of thumb" estimate, assuming ~77ohm air-insulated coax with an inside diameter of the outer conductor of D inches, at frequency f MHz, Qu will be about 100*D*sqrt(f). So a 1" line at 100MHz will give you Qu about 1000. This quick estimate may be all you need, and even quicker than loading a program.

I trust you are aware that the Qu won't tell you how sharp a filter will result; for that, you need to know the configuration and the loaded Q--or better, where the poles and zeros are. There are lots of ways to do that; RFSim99 might be a useful (and free) tool for you. By appropriately tapping the thru-line down on an appropriate stub, you can arrange to pass one specific frequency with very little disturbance while blocking one other specific frequency of your choice (and another you don't have so much control over, and of course others at multiples of the lowest freqs). Or you can combine a stub that blocks a particular frequency with a reactance (capacitor or inductor) that tunes out the reactance of the stub at the frequency you specifically want to pass.

For example, put a 77-ohm shorted stub that's a half-wave long at 125MHz across your line, and you notch 125MHz. Put an 18.8pF capacitance across that, and you will pass 150MHz with little effect, because the 18.8pF resonates the inductive reactance that the stub represents at 150MHz. But it will also pass 46.5MHz with little effect. Put about 27nH across the same stub and you'll notch 125 while nicely passing 115MHz. Include line and inductor loss in the model to see the depth of the notch and the attenuation at the "pass" frequency.

Cheers,
Tom

Iive started doing that -- on a ng-by-ng basis -- when it appears to Get
Out Of Control. Now it looks like I need to start killfiling the google
followups in the rec.radio.amateur.* collection.

It's so frustrating to follow some 'interesting' thread over a period of
days and be forced to stumble through a number of thoughtless,
disembodied followups.

sigh...

Something like a 2" copper pipe centered in a metal garbage can?

Or, 19" of RG-174?

Jonesy

Don't bother with the CRT, look for the drivers instead. These was typically a penthode PL509 tube or the US equivalent. These makes very nice linear pa's and was often parallell connected. Four of them made a good 500Watts pa when fed with 1300Volts. The power supply for these pa's is normally made by doubling the mains power... very nasty but also very very cheapo!

Cheers

With the holiday season here it is time to redo the workshop and the
workbench in particular.

So, what suggestions do you have for setting up a good efficient
workspace for electronics?

Here's an example that I found....

http://www.stevenjohnson.com/workbench.htm

So what does your workspace, test bench and layout look like?

Pictures and links would be great.

What has worked for you?...what hasn't?

Benches, racks, cabinets, tables, carts....

Any particular test equipment that you would recommend for or against?

Thanks

TMT

If you're interested in building (with surface mount components), see:
http://www.w1ghz.org/222xvtr/222.htm

Small board. Designed to use Yaesu FT817 as an I.F. rig, but any rig that can provide 24 MHz at 1/2 Watt is useable. Transverter puts out 5 Watts, so an external amp could be used to boost output if desired. I have the circuit board for it, but it's not built yet, so I can't comment much. A friend has one and hasn't said anything bad about it that I'm aware of...

My workbench looks like an absolute fright unless I've been very
unproductive (and therefore have had time to clean), or I've reached a
standstill (and therefore must clean).

Otherwise I just look at the pile and ask myself how long ago I used a
particular tool, then I look that far down to find it.

I like the pictures of the shop..really neat and clean..I have worked in radio for about 60 years and you get sort of "set in your ways".. I like to work on a roll around cart about 24 X 30 in. 28 in. heigh.That way you can have test equip and tools within reach..I have all the digital test sets and I always have an analog meter,like Simpson 260 and Tripplet.630 ...Also I have a complete soldering station with everything modern,,but I always have a gun or two on the bench also..For boatanchors you really need some analog stuff,like HV multimeter to 6000 volts etc..A maglight is a must for close in work..A good assortment of power supplies,from 0 to 50 volts regulated and a good 12 volt PS at about 30 amps.or more..A good scope to at least 50 Mhz,preferabily 100/200 mhz.If you get a Tektronics scope you can attach a didital counter to the scope (ch.1 out)and read frequency as well as pattern.Helps when working on freq .multipliers etc..Just some ideas and suggestions..Good military Test equip. is available for pennies . repairing it ,not always easy..Good luck W4PQW

Oh deep joy !!! That is a perfect description of my workshop. I wish I
could keep it looking like the pictures in the post above. I have as much
benchspace, but on an average day, probably about 18" to 2 foot available

...

On another similar sized bench behind me, I have one of the workshop computers, the weather sat receiving equipment, and my amateur radio station. On that bench, on a good day, there's just about room for the station logbook !

Those look like part of the bench - I know some of the brands of benches
available used to have the plugs there. My benches have a 6' strip with
plugs every 3 - 4" that we bought from I believe Tripp Lite last summer.
They were quite reasonable with a lighted, covered switch, circuit breaker,
a 10 to 15' long heavy grounded cord, with a nice extruded aluminum housing
for ~$70 CND @ something like 7 qty. They make many styles and lengths.

Size of stuff to fix upon determines the design of bench and tools.

I'm TV tech;
Big ones like 36'ers demands at least 5 feet by 10 even more feet
bench to allow for tools to lay besides the unit. I have wished I had
that because of few CTC210/DTV306/etc that needed the depth so I can
push the unit way forward so I can eagle spread the crowded chassis
that weighs a tonne and clumsy to handle just to freaking replace 10
parts in worst places. Lot of chassis flipping just to see as you put
new parts in and remove and resolder transformer for that R14609 tiny
10 ohm resistor that's now a black crater, that D14611 did to
components in standby SMPS.

Be make sure the bench is high enough so you don't bend over so low
but not too high to heft heavy TV up there. Flat CRTs are heavy!

Cheers, Wizard

The TekScopes group on Yahoo did this awhile back, too. Lots of fun to
look at other scope junkies' benches.

I dont do much tronic work now, but just did some today. A lot of the
things I found are just as true in what I do now though.

The no. 1 handy thing is a little hand held probe that amplifies and
send the signal to a piezo. Its an imprecise but very quick way of
finding out roughly whats going on here there and almost everywhere.

The one thing I avoided like the plague, and still do, is those plastic
drawer racks with often open top drawer boxes. You've only got to move
one once to see what I mean! One spill and you'll never ever buy one
again. Small parts containers must have burst proof latches, I wont use
any that dont.

Domestic chipboard chests of drawers are a good quick cheap way to get
storage space in situations where you can be sure nothing will be put
in front of them. Especially good where your storage expands into
living space. They sometimes need reinforcing, ie more runner screws
and gluing draw bottoms in. Yes its ok to do that with chipboard
drawers (not with real wood ones tho).

Wooden shelving has the advantage that its easily made in any size,
weight and shape to suit your workshop. And with any features you want
on it. If you want large quantity or heavyweight, its also less money

than large amounts of steel. A lot slower to put up, but much more adaptable. Shelving racks of all kinds can have overhead linking bars betwen them to make them rock steady. Realise a shelving rack collapse can kill, they must be rock steady.

If you can take a photo of your workshop, youre failing to use a lot of the space.

Cardboard boxes have always been my favoured storage cases, as they offer some amount of protection in case one is dropped, and theyre freely available at any time, which is also important. And any size. As I've found, always label them!

For the ultimate in space efficient storage theres always tracked shelving racks, but theyre not cheap. Metal racks on tracked wheels, with a big knob/lever that you turn to move them. One only need maintain one gangway between the lot, move them to enable to get to where you want. Very effective if youre storing on a larger scale, and space is expensive, as it is here (very). A serious space saver, but access is slower. Fill them in order of whats most used to minimise moving.

Soldering guns I've found almost useless. Theyre not good performers, and how many jobs are done so fast there isnt time to do something else while an iron heats up? Havent used mine in so long I dont even know where it is.

Gas lighting has proven more reliable for power cuts than battery, though these days battery exit lights are now common.

NT

I moved over 1000 miles in 1987 and I had 24 50 drawer Akro-Mills
cabinets full of parts. I cut pieces of cardboard to cover the front and
placed two of them face to face, then taped them together. I didn't
have even one part out of place when I arrived at my new place and set
up my shop. The move was done with my shop's step van and I hauled over
17,000 pounds of tools, parts, manuals and test equipment in two trips.
there is nothing wrong with parts cabinets, if you know how to pack
them.

The last time my bench was clean was over a decade ago - after I learned I had a very aggressive form of cancer. I reluctantly cleaned off the bench to save my wife from having to do it.

But, through the miracles of drugs, the cancer went away. Now, my desks are all cluttered again. My wife fondly talks about how good life was when my desk was clean and I had sold much of my junk. I think she is kidding, but would not bet my life on it.

When I clean an area, it is only temporary.

At the constant prodding of my wife, I spend 3 months cleaning up the floor of my darkroom. I found things that had been missing for years. But, I could not clean up the desk, for it has all the little parts for which I do not have a place for.

In the end, messiness is really just the product of someone who has so much order that he insists upon a place for each item before he puts it away.

Gee Whizz this 36 inch I have weighs in at 200 pounds.
Maybe you need to think about a motor hoist with straps or something.
I know by myself this TV will never be moved. Maybe it can sell
with the house some day. Good luck with the hernias.

I have a 12 X 24 patio I am thinking of enclosing and making a shop...
so I am following this thread too. lol where ever it goes

That's an amazing shop. My own is unfortunately nothing like it, far more cluttered with junk piled all over the place, I suspect it's typical of other hobby techs here.

I suspect it all comes down to how you use them. Where I had mine,
there was no room to mount those cabs on the wall, so accidents were
inevitable... and could take forever to clear up. If yours are screwed
to the wall, no worry.

Space costs vary widely around the world, and here things are pretty
cramped. So much so I wouldnt really want to post a pic. Reading of
folk with 14' benches makes my brain boggle! Fanciest I ever had was
6', the worst was... well theres space on top of those boxes.

I imagine in Hong Kong it would be a case of, well, this one should fit
on the laps of your 4 roommates, who could sit their keyboard on top of
the screen so they can continue typing. Maybe one can rent desk space
there, wouldnt be surprised.

YOU CALL THIS A WORKBENCH!?!?!?
my Goodness, if the mess on mine is les than 5 inches deep I feel I
didn't do anything on that table! You know, I trained myself to
identify location of things by the sound they make when they fall on
something else when I throw it aside. If I were now to mop it up , I
wouldn't be able to find anything!
In any case I wish you good luck and I congratulate you for the
initiative.

Reminds me of one guy who complained that he could never find the chuck
key for his drill, so begin buying them by the dozen -- that way, he said,
they normally last for a week or two! :-)

I have a Heath SB200 that has been modified a bit too much.
Someone replaced the stock fan with a muffin fan and they
cut a big hole for the fan in the RF chamber.

I want to replace the muffin fan with a fan resembling the
stock fan. Grainger sells motor and fan blades for appliances
that look close enough. I just need some data to choose the
right one. Most import is the fan blade size. Second would
be any specs for the motor. Stock motors range from 1/500Hp
to 1/20 HP. I suspect one of the smallers one based on physical
size.

Also the meter seems to stick in a couple spots. I don't
see anything obvious like a bent needle. Any hope of finding
a similar meter that I can move the faceplate? Any place that
can repair meters?

All help appreciated.
thanks
chuck

Often, especially in the winter months, due to static electricity.

See if wiping it with water or an anti-static cloth helps.

Tim.

In W4OP_2, what's the rightmost gadget? The one in the gray case,
with the meter(?), some gray knobs, and 2 toggle switches on the
front, and a black box on top of it? There's a printer behind it.

Looks like you've got good taste in CAD tablets, too.

While I haven't built my bench yet, I've been planning it a Looooong time. I've assembled this list from having lived in my dads shop for 15 years and worked at various research labs for 20....

1. Desktop - I prefer a deep top, on the order of 40" or more. Reason being that when test equipment becomes attached to larger devices (i.e., TVs), space becomes a premium, and laying a schematic on a hot chassis is not a good idea ;).
2. I like the top shelf idea but would use it for test gear that doesn't need to be watched or interacted with a lot while in use. Scope and logic analyzer on the bottom, Frequency generators, PS, etc on the top. A verticle shelf of test gear along the side works good for me.

3. Lots of outlets/wire mold. Wiremold along the back with 1" x1" panduit wireway to keep the power cords routed.

4. Power cut off switches for parts of the bench.
5. power conditioning for all of the bench (CV transformer/harmonic neutralizer), Also GFI protected.
6. Work lights - magnifier, fluorescent and incandescent. Why incandescent? Floursecent are such great RF radiators and influence some of the gear I design/work on.
7. VTVM and DMM (I am old fashioned - Depending on what I am measuring, I like a meter that can withstand "hitting the wrong testpoint"
8. Test lead, jumper clips hanger - Use 1"x1" panduit with one side cut off for hanging test leads.
9. storage shelves. For components, I like 6-9" deep, for test gear, etc., I like 24" deep.
10. IC storage. I tend to keep lots of ICs around. I like to keep them in the plastic carrier strips, cut a hole in one end and hang them.
11. PC and inventory control. I know this sounds a bit overboard but...print out barcode and attach to every spare part before stored. Scan when used. Keeps an inventory in a DB of parts. You have no idea how many times it was my job in my dads store to look for a part that he 'knew' he had. Also, since I collect old computer 'stuff', It is nice to have an inventory list.
12. A separate section or separate bench for 'fabrication' that would contain drills, hammers, vise, etc.
13. One idea that I saw for a woodwork bench that I like is a number of verticle, slide out, pegboard pieces (about 2-3' high and 2' deep that sit under the bench. The are verticle, perhaps tilted back slightly, and can slide out. Organize tools, whatever. Keeps them from being piled in drawers and saves time hunting them.

14. Get service data in electronic format. Get a scanner and PC. I grew up with and still have tons of service manuals and data books. Using PDF versions of all this stuff saves time and space. If I could only get my 15 yo data books on DVDs I'd be soooo happy...
15. Antistaic mat on benchtop and also floor pad (or paint, depending on situation)
16. I have often found the need for a hefty heat gun (in lieu of a reflow furnace, and also to remove components in mass...lol)

17. A 'L' shaped bench works better for me than a long one. Also, ppl sometimes put pegboard on the back of benches to hang stuff..I don't like that because I don't like reaching across my work. Personal preference.

18. If you do serious work, I recommend mainstream test gear (HP, Tek, Fluke, etc.). You can trust what you measure. I know cost is an issue, which is why I'd get good used gear. For example, I'd get a good used Tek 465B, 475 or 485 over the newer DSOs. Most of the time, I don't need color, I don't need it connected to my network, etc. (But I do have one just in case...)

I've build this bench many times in my head and even started it in my basement, but never time to finish.
Good luck
John

You're supposed to ty-wrap it to the cord, out at the plug end, so that
you can't use it while the drill is plugged in. (Keeps your hands in
one piece.) :-)

Cheers!
Rich

Hi Mike,
That's a General Radio 1236 meter I use for measuring sun and moon noise on
my 1296MHz moonbounce station. It is a 30MHz IF amp with decibel meter. In
the extended mode, I can easily resolve 0.05dB changes. Sun noise
measurements are an excellent standard by which we judge system efficiency.
On 10GHz I can see about a dB of moon noise- which is also handy to keep the
dish trained on the moon.
That pix is pretty dated at this point- the 746 has been replaced by a
756PRO II and the SSB transverter has been replaced by a DEMI 1296-->28 MHz
transverter.

Thats assuming that this is a Tube Chassis TV Set which are rare
collectors items these days.

Just junk the sets and start with some technology thats been used in the
last 25 years or so.

That doesn't work on my drill press. Its chained to the wiring cover
on the motor and only has a couple inches of slack to keep it out of the
way.

Hmm, then maybe you need a little bungee for it. :-)

Hey! I just had an invention! The chuck key plugs into a dead-man switch
socket! It's right there on the drill press, and you pull it out, it kills
the power, you use it, and you have to poke the chuck key back into its
socket or the drill press won't turn on! ;-)

Nah, they'd defeat it with a nail or something.

Good Luck!
Rich

If you combine that with a self sealed relay as the run contact
(momentary N.O. pushbutton to start, momentary N.C. pushbutton or
pulled key to stop) I think it would be just great. I just wouldn't
want the motor to start at the moment I plugged the key in the hole.
I might just add that to my press.

5882. To build or not to build

If everything works out this weekend I should have about 10w or so to drive into a linear. My friend here in town thinks I should buy used Dentron Clipperton or Heathkit. I don't think 10watts would do either justice. If 10w would give me a KW out with a commercial unit I would consider buying a good used unit.

Plan bravo is to build. I would have to do tubes in keeping with the theme of that side of the shack. CW, AM, & SSB are all modes that I would operate. I only need to operate 160m - 40m. I am experienced transistor engineer and my early schooling was in tubes , so not beyond my reach for this type of a project. I have plenty of other homebrew projects to keep me busy if this one gets scratched.

I need help picking a topology and a tube set. Price and likelyhood of getting the thing working are two top runners. From the 1965 ARRL Handbook I see a few different tubes that might qualify. A Pair of 813 in parallel, 3-400Z, 3-1000Z. I am soliciting some opinions on the topology. Again, all I got is about 10w am going into. I would like to do a kw or so pep. I am not looking to buy any parts at this time, so not looking for any 'sales calls'. I need comments like - look at this tube with this plate voltage kinda thing. Or try driving this toob with a such and such to get a kw out. I would like to keep the design required to a minimum and would consider some 'reverse engineering' a plus at this point. If I can get most of the design out of an old ARRL handbook then that would please me.

Not new, I installed one of those on the drill press where I used to
work, more than 20 years ago. Guys kept leaving the key stuck in the
chuck and then turning to motor on... Not good.

==========
That's a 20dB amplification ...a bit much for a single stage amp.
You need a 10 dB intermediate stage ,resulting in 100 W output.
The final 10 dB to 1 kW can then be achieved with a (standard) Poweramp.

The usual 6146 final stage doesn't take in more than a couple of watts
for 100 watts out.

I don't play with heavy iron, but AFAIK most linear amps are limited to
10dB of amplification because most hams have 100W output rigs and the
FCC kinda frowns on non-home-built amps that can do more than that
(something about CB'ers).

I've seen tetrode amplifier designs that look like they could easily do
this. You'd have to actually _pay attention_ to isolating the input
from the output, and you'd have to do all the care-and-feeding stuff
that screen grids require, but it should be possible to do it in one stage.

4CX1000.

Parts *relativly* easy to obtain.
Mechanically strong.
Complete plans in ARRL handbook.
KW+ all day on less than 10W drive.
Wants a bit under 1Amp at 2.5 - 3kV
If possible, get the 'K' model rather than the 'A'. Not so much for the
frequency response as for the more robust screen. If your budget doesn't
stretch to the genuine Eimac, try a copy such as Svetlana's 4CX1600.

Frankly I don't think 10W will drive any linear to 1kW.
You will get the most gain from a Tetrode but I still
don't think it will go 20db. I suggest you search for
richard measures web page and read some of his articles
about the merits of GG vs grid driven amplifiers.

I think you will need an intermediate stage to get
enough drive. Then you might as well pick up an old
Heath SB200 or SB220 for the final stage.
The SB200 will give you 500-600 watts out with a
pair of 572s and you can buy them for 300 bucks.
Plus the tubes are not too expensive if you need new ones.

chuck

Hi Chuck.

I have a SB-200, but I don't have the time to take it apart and
measure the size of the fan right now. Maybe this weekend.

In the meantime, you might load and/or ask here:
http://www.harbachelectronics.com/

He sells replace parts for SB-200, SB-220 and others.

That's true in grounded grid mode, but quite doable for grid driven.
According to the Amperex data sheet, a pair of 3-1000Zs in class B
grid driven mode will give 3560 watts out for 28 watts of drive. For a
single tube, that scales down to 127 watts out per watt in. 10 watts
in will give 1270 watts out, a power gain of 21 dB.

That's the only tube I've looked at so there may be others that will
give a full 1500 out for 10 in. On the other hand, 1270 is close
enough to 1500 that you'll probably never notice the difference.

You will have to neutralize it of course, lest you end up with a high
power VFO. :-)

Not much industry experience, huh? ;-) I only mention it because almost
every major industrial-grade tool I've seen has "ON" and "OFF" buttons,
and a latching contactor. If power goes down, or the "OFF" button is
pressed, or the "EMERGENCY STOP" button is pressed, the machine turns
off, and doesn't restart when you reset the breaker - you have to
overtly press the green "ON" (or sometimes "START") button. This gives
you a chance to clear the scrap out of the machine before you reset
and restart whatever process got stopped in the middle.

Probably cost-prohibitive for a consumer-level garage or basement drill press.

Then again, people pay for explosives inside their car in the name of "safety"; why not add fifteen or twenty bucks to the cost of a power tool if you can tout it as a "safety" feature? ;-P

Thanks!
Rich

>don't think it will go 20db.

Most modern tetrodes will easily provide 20dB of gain, and with good stability.

The favored technique is to use an untuned grid circuit which is resistively loaded (often called 'passive grid').

In class AB1, grid-driven, a tetrode requires very little RF input power (in simple theory, none at all). All the grid requires is a voltage swing. For good linearity, the tube should never be driven into grid current - in other words, even at peak RF input voltage the grid should never become positive. That means the peak RF voltage should only be equal to the grid's negative DC bias. These basic requirements are totally independent of the output power capability of the tube.

For tube data, see:
http://www.g8wrb.org/tetrodes.shtml

The driver stage will need to see a 50 ohm load impedance, so the most common input circuit in commercial tetrode amplifiers is simply a 50 ohm resistor. However, 10W into 50 ohms is only 31V peak, and a typical value of grid bias is probably about -50V (depending on the specific type of tube and its recommended DC bias conditions). It is quite true that 10W could not drive such an amp to full output.

But you're not forced to use a 50 ohm input resistor. Think about using a broadband step-up transformer to get a larger voltage swing.

For example, a unun transformer with a 4:1 impedance step-up, terminated in a 200 ohm resistor. This will provide a 50 ohm load to the driver stage, and 10W will deliver about 62V peak to the grid of the tube. So any tube that will operate in class AB1 with a grid bias of 62V or less can be driven to full output by 10W.

10W into an input circuit consisting of a 9:1 unun terminated in 450 ohms will deliver about 93V peak. This is more than enough to drive any modern ceramic tetrode to full output, so the driver stage can actually be operated at significantly less than its 10W maximum, for improved intermodulation distortion.

It should be quite easy to find or develop a suitable broadband transformer design, especially since the original poster only wanted to operate 160-40m.

I prefer the small chain. If someone turns the drill press on with it
in the chuck there is a weak link that will snap and not whip the chain
all over the place.

I've got a scrap bench top drill press that was built with a switch
lick that. Its the second one my dad has killed in the last seven
years. You couldn't flip the power switch on the first one, till the
chuck key was wedged into the hole.

Well, the one I got at the supermarket for some 40 euros has one.

They're actually simple devices: a switch where the latch is a tiny
coil. Not expensive at all, if made in sufficient volume.

A little off topic, but air bags don't protect anything. People have air
bags and now think they can drive more aggressively as they are
"protected." Four-wheel drive also makes people drive in conditions they
normally would not; but four-wheel stop is the same for both.

Lots. I just described it for those who do have not seen this common
control circuit. And, sadly, most home power tools have no such

control circuit.

If he doesn't care about absolute accuracy, series or parallel mode is not
a concern. The LC tank will reduce phase noise, but shouldn't have a Q of
more than about 10-20. If you tune the tank for max amplitude, you are sure
to be at the right operating point for the xtal.

Ok, lots to think about here. I figured 20db would be a lot to ask out of production unit. Tim's made a couple good points. A Tetrode may be a good way to go, but I wonder if a 4146 driving into something else might be a bit cheeper. Maybe a pair of 813s? As I said the 1965 ARRL handbook claims a kw out with a pair of 813s,but I have my doubts. They are cheep enough - $55 ea at tubesandmore.com The Taylor 572B can be had for about 200 bucks for 4 of em. Would this be a viable option?

I wonder if the 4CX1000 or 3-1000Z solutions can be done for a good cost relative to other implementations. Also, are they easy to get working? I'm afraid I might end up chasing parasitic ghosts. I am aware that layout can be critical and would look to clone somebody elses design that's up and running if that's the way I go.

Thanks for the comments. I thought it was narrowed down to a large tetrode with a lot of gain or two stages with 4146 maybe driving 813s or the 572Bs that get run in a lot of commercial rigs. Then I realized I would have to buy a plate transformer and a chassis and a box and a whole bunch of other stuff. Right about now some kinda intermediate predriver to get between the 10w out and the 100w in that I need might not be a bad deal. Then again I really need to buy from somebody I trust cause I hear a lot of people whining about used linears they bought. So nothing is decided.

~~~~~~

(I assume you meant 6146 in the above)

Remember, adding a driver stage complicates the design because you
will have to add bandswitching to the driver too, unless you can
figure out a way to broadband a tube amp, something not easily done.
If you grid-drive the 6146 you will have to add neutralizing as well.

A pair of 813s have only 250 watts plate dissipation. Getting 1kw out
of them is pushing it and their life will be short. For just a bit
more you can get a single 3-500Z and have twice the plate dissipation.
This is still not the best way to go, IMO. If you are really stuck at
the ten watt drive level, the class AB1 tetrode passive grid solution
would be the best approach.

Big, strong amplifiers are not cheap. Don't scrimp or you'll be sorry.
Are you aware a 1500 watt rated bandswitch will cost about as much as
a PAIR of 3-500Zs? And that's only the beginning. Plate transformer,
power diodes, filter capacitors, tune and load capacitors, chassis and
cabinet, blower, on and on.

Homebrewing a high power amp is a prestigious accomplishment, but in
terms of overall cost, buying commercial is cheaper in the long run.
The money you spend on a homebrew amp will likely never be recovered.
A commercial amp can retain a large percentage of it's price when the
time comes to sell. In fact, if you buy a quality used one you might
well be able to use it for years and sell it for more than you paid.
Something to keep in mind.

My wallet hurts just thinking about it. :-)

73, Bill W6WRT

For plastic meter faces get a soft cloth and some liquid dishwashing detergent. Use the detergent straight, no water and wipe the meter and then buff so none remains. This has worked for years on the heath VTVM when static builds up.

A number of potential recruits are in great danger of being misled into thinking that they are Radio Hams when, in fact, they are nothing of the kind! As it is the season of goodwill, let us show our goodwill by saving these poor deluded fools from the mischievous ne-er-do-wells who will attempt to mislead them. (Radio Hams are technically-motivated people and not merely turnip-brained button pushers like CBers and like M3/CBers)

What is Ham Radio?

Ham Radio is a technical pursuit for those who are interested in the science of radio wave propagation and who are also interested in the way that their radios function. It has a long-standing tradition of providing a source of engineers who are born naturals.

Ham Radio awakens in its aficionados a whole-life fascination with all things technical and gives an all-abiding curiosity to improve one's scientific knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience with ones fellow man, and shows itself in the gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that they can construct and operate their own equipment! No-one else has this privilege. Users, such as broadcasters, the po lice and armed farces, CBers and mobile phone users have to purchase ready-made gear. Manufacturers are not licensed to operate their gear. Radio Hams are qualified to design, build and then operate their own pieces of equipment. They do this with gusto, and also repair and modify their own equipment. This is a privilege well worth the effort to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with relatively simple technologies at first, perhaps making his own Wimshurst machine and primary cells. Small pieces of test equipment follow, possibly multimeters and signal generators. Then comes receivers and transmitters. It is with the latter that communication with like-minded technically

motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of

a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B
licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

Happy Solstice, and let's keep the religious crap out of Crapmas!

You seem to be intellectually challenged on the point that
you make below (CBer, are you?) - the essence of a
discussion group is,.....wait for it.....discussion!

Discussion implies talking.

ITYM, "too" and not, "to". (CBer, are you?)

Turns out that if you really want micropower sinewave oscillation at
32kHz, you are far better off using bipolar transistors than CMOS gates.

The Pierian Spring, from Greek mythology, was a source of inspiration.

I see nothing inspiring in the bigoted drivel you just posted.

Pierian Spring, aka Gareth Evans G4SDW, was once a member of a church
bellringing group. One wonders what happened in the belltower that turned
him so....

If you publish Childish Broadcasts (CB) such as you
do below, then you will be perceived as a CBer.

Ham Radio is a technical pursuit for which it is
important to maintain standards. There is no
bigotry in seeking to maintain educational
standards.

We do ourselves no favours if we associate
with the non-technical turnip-brains.

Grow up, Mike Gathergood!

If you wish to be perceived as a Childish Broadcaster (CBer)
then continue to publish Childish Broadcasts (CB) as you
do below.

Ham Radio is a technical pursuit with gentlemanly
traditions, traditions which seem to be lost on you.

Roooooooodney wrote:
> You should check into the Liberty Net at 10:00 PM

Your knowledge of the Pierian Spring is shallow if your only
association is through Pope's reference.

If, however, it is merely the case that you wish to be
perceived as a Childish Broadcaster (CBer) then
continue as you do below.

Just got this from my pal in Texas...
It hits the nail on the head :-)

Peter, G3PHO

..... TOOL TALK .....

DRILL PRESS: A tall upright machine useful for suddenly snatching flat metal bar stock out of your hands so that it smacks you in the chest and flings your beer across the room, splattering it against that freshly painted airplane part you were drying.

WIRE WHEEL: Cleans paint off bolts and then throws them somewhere under the workbench with the speed of light. Also removes fingerprint whorls and hard-earned guitar calluses in about the time it takes you to say,
"Ouch...."

ELECTRIC HAND DRILL: Normally used for spinning pop rivets in their holes until you die of old age.

PLIERS: Used to round off bolt heads.

HACKSAW: One of a family of cutting tools built on the Ouija board principle. It transforms human energy into a crooked, unpredictable motion, and the more you attempt to influence its course, the more dismal your future becomes.

VISE-GRIPS: Used to round off bolt heads. If nothing else is available, they can also be used to transfer intense welding heat to the palm of your hand.

OXYACETYLENE TORCH: Used almost entirely for lighting various flammable objects in your shop on fire. Also handy for igniting the grease inside the wheel hub you want the bearing race out of.

WHITWORTH SOCKETS: Once used for working on older British cars and motorcycles, they are now used mainly for impersonating that 9/16 or 1/2 socket you've been searching for the last 15 minutes.

HYDRAULIC FLOOR JACK: Used for lowering an automobile to the ground after you have installed your new brake shoes, trapping the jack handle firmly under the bumper.

EIGHT-FOOT LONG DOUGLAS FIR 2X4: Used for levering an automobile upward off a hydraulic jack handle.

TWEEZERS: A tool for removing wood splinters.

PHONE: Tool for calling your neighbor to see if he has another hydraulic floor jack.

SNAP-ON GASKET SCRAPER: Theoretically useful as a sandwich tool for spreading mayonnaise; used mainly for getting dog**** off your boot.

E-Z OUT BOLT AND STUD EXTRACTOR: A tool ten times harder than any known drill bit that snaps off in bolt holes you couldn't use anyway.

TWO-TON ENGINE HOIST: A tool for testing the tensile strength on everything you forgot to disconnect.

CRAFTSMAN 1/2 x 16-INCH SCREWDRIVER: A large prybar that inexplicably has an accurately machined screwdriver tip on the end opposite the handle.

AVIATION METAL SNIPS: See hacksaw.

TROUBLE LIGHT: The home mechanic's own tanning booth. Sometimes called a drop light, it is a good source of vitamin D, "the sunshine vitamin," which is not otherwise found under cars at night. Health benefits aside, it's main purpose is to consume 40-watt light bulbs at about the same rate that 105-mm howitzer shells might be used during, say, the first few hours of the Battle of the Bulge. More often dark than light, its name is somewhat misleading.

PHILLIPS SCREWDRIVER: Normally used to stab the lids of old-style paper-and-tin oil cans and splash oil on your shirt; but can also be used, as the name implies, to strip out Phillips screw heads.

AIR COMPRESSOR: A machine that takes energy produced in a coal-burning power plant 200 miles away and transforms it into compressed air that travels by hose to a Chicago Pneumatic impact wrench that grips rusty bolts last over tightened 50 years ago by someone at Ford, and neatly rounds off their heads.

PRY BAR: A tool used to crumple the metal surrounding that clip or bracket you needed to remove in order to replace a 50 cent part.

HOSE CUTTER: A tool used to cut hoses too short.

HAMMER: Originally employed as a weapon of war, the hammer nowadays is used as a kind of divining rod to locate the most expensive parts not far from the object we are trying to hit.

MECHANIC'S KNIFE: Used to open and slice through the contents of cardboard cartons delivered to your front door; works particularly well on contents such as seats, vinyl records, liquids in plastic bottles, collector magazines, refund checks, and rubber or plastic parts.

DAMMIT TOOL: Any handy tool that you grab and throw across the garage While yelling "DAMMIT" at the top of your lungs. It is also the next tool that you will need.

EXPLETIVE: A balm, usually applied verbally in hindsight, which somehow eases those pains and indignities following our every deficiency in foresight

Gene-

Converting a modern frequency-synthesized radio to receive different frequencies may be possible, but quite a neat trick.

A simpler approach would be to buy or build an external tuner. It could be crystal-controlled, switching between crystals for different frequencies. It could use only one crystal and use the existing radio's tuner to select different frequencies.

Hey Bill you got some really good points there. (Yes, 6146)

I figured a homebrew Amplifier project could be a costly undertaking. I got over $500 into the HX-50 with the cost of the unit and parts to get it running. I had about 80 hours into a Knight T-150 to get it working correctly. Was my first rig and I called it a learning experience to ease the pain. The reason we play with these radios is because we like to rather than to make any money at it.

I've got a few big mosfet projects in front of the amplifier, so not in any hurry. (I can do a full PEP setup with a half dozen fets for about 200 bucks.) I'll do some more poking around and see what I come up with. Project may in fact become a reduced output amplifier.

Thanks everybody for comments. I will mull over and figure this all out as other projects get finished.

Yes morse is obsolete, but also useful.
The former is no basis for banning it.
The latter is no basis for using it as a passport to the HF Bands.

Why do we need a further exam for incentive licensing? Do we not have enough already?....
(1) CB licence as an appetite whetter
(2) Novice licence
(3) RAE.

(Perversely, the Novice RAE is a higher technical challenge than the RAE!)

Restore the RAE to its technical status, and we have a sufficient and complete incentive licensing scheme, without anything to do with the Morse (Sorry, Vail) Code.

Arguments relating to international requirements are redundant - laws change.

Amateur Radio is dying, and this is due IMHO in no small part to the consumerism CBish activities of today, QSLing as an end in itself, WAB, contest operating other than as a means of evaluating one's technical equipment, squeakies on repeaters, walts on URA, and inane discussions

about the turnips growing in one's garden.

Scratching my head again...

This is specific to the AADE unit.

I've got a coil of about 5mH. If I use the C function of the AADE I get a reading in the range of 25 pf.

Am I seeing the actual interwinding capacitance here or is the combination with inductance goofing on the measurement circuit that this device utilizes?

If it helps anyone get a "feel" for the amount of capacitance of this coil its about 175 turns, #37-ish loosely scatterwound in about 1.5" diameter, 1/8" wide and high.

TIA,
Bill WX4A/KP4

Thanks for the responses so far....

A few more questions....

How much and what type of storage do you have?

How are the workbenches laid out most efficiently? L shaped? U shaped?
T shaped?

How much stationary and how much mobile?

What do you like for lighting?

Has anyone built power busses into your bench? If so, what was it?

How about floor coverings? Ever drop a tiny screw or surface mount part
on the floor and spend hours looking for it?

Actually, in theory it is pretty easy, in practice, darned near impossible. Given that the railroad and 2 meters are neither very far from the weather band, you probably could get reasonable performance without any front end changes.

But here is the problem ... in the old days that tuning knob was attached to a variable capacitor and a slight change in the L and C values could move the radio. Today, however, that knob is attached to an encoder that is read by a microprocessor. The micro then tells a synthesizer what frequency to make. So, it is a simple matter of reprogramming the micro.

There's the rub. Even if you had the capability to reprogram the micro (really not all that unreasonable) you would need to get the source code (not bloody likely). And if you had the code, simply understanding it would be a major challenge; I was visiting one auto manufacturer a few months ago and was surprised to learn they have over a million lines of code in the radio!

This, actually, could be pretty simple. You are only a couple MHz away from the railroad frequency, so some sort of front end filter, a 602 with an appropriate crystal, and a whopping attenuator on the output of the 602 and you should be good to go. You could do something similar for a repeater, the rock would be more like 20 MHz instead of 2, but you couldn't cover much of the 2 meter band with the tuning from the weather band. But for one repeater...

The ugliest part would be switching it in and out if you wanted to listen to the FM Broadcast band.

I'd guess the effective parallel capacitance is quite a bit less than
that. Not sure just what's going on in the processor in the AADE to
figure out and display that number, but remember, the circuit works by
looking at the resonant frequency of a tank that includes your part,
and by asking it "capacitance" when you clearly put "inductance" across
the terminals is...um...asking for trouble or nonsense. You might pose
the question to AADE.

Cheers,
Tom

I had a Nissan/Clarion radio that was stock for models exported to the
"English Caribbean". It was set for 9 kc AM-BC channels and had no
switch as an option. No importa that the Caribbean doesn't use 9kc
channel spacing. The switch placement markings were on the multi-use PCB
but it wasn't there. I'm sure there was a workaround but without
supporting documentation it wasn't to be done...at least not by me.

In the case of the Weather Band....since there is more than one freq in
use, do you have any channel option there (WX1 or WX2) or is it just so
broad that it will receive any Wx-band channels?

I also suspect that this LO freq is programmed into the chip. They
don't really make them "hobbyist-friendly" do they?

I have a new in the original box F455N20 collins filter
(from R390A) that I got at a hamfest many years ago
and stored it away for a 'future project'.

I dug it out recently and was examining it when I noticed
that as I rotated it in my hand I could feel something
inside shifting back and forth. I never noticed this
before (the filter was NEVER dropped in my care and
has remained packed in the original packing material
all this time). Is this normal for this type of filter
or might the unit be defective?

As others have pointed out you will need a tetrode amp to get
20db of gain in one stage. The old warhorse 4cx1000a will do it,
but this is an expensive tube with an expensive socket to match!

Look for a Svetlana 4cx800 tube. The sockets for this are not
too costly and the tube itself is in the $100-$150 range. A single
4cx800 will get you close to the legal limit. You can drive this tube
as a conventional grid driven with tuned input, or use an impedance
matching transformer with a 450 ohm swamping resistor.
Yet another way is to run the tube cathode driven, but with normal
grid bias and screen voltage, both grids bypassed to ground for rf.
I'm not sure how much drive will be required in the cathode driven
mode, but if operated in AB1 it will be much less than a conventional

grounded grid circuit.

"Micky Taker" is, in reality,

Eric Williams, M3EJO,
19, Raglans,
Exeter,
EX2 8XN.

He is one of those disgraceful adults warned against by the OP; a grown man with seeming years of experience who was either too lazy or too stupid, or both, to be able to tackle and pass exams that were being taken in their stride by otherwise-unqualified 14-year-olds and went instead for the yellow-bellied coward's way out by going for exams set for 6-year-olds.

Eric did not seem to understand that the OP was a public stance for the maintenance of academic standards and that by responding with his Childish Broadcast (CB) in the way that he did he illustrated graphically the sort of turnip-brained dross that the OP warned against.

M3EJO is one of the licences issued under the gangrenous degeneration that is the M3/CB Fools' Licence and by taking out such a licence, Eric proves himself to be an incurable CBer who will _NEVER_ make it into the ranks of _REAL_ Radio Hams.

Eric seems to have missed the point that the OP was arguing in favour of the very acadaemic standards that Eric himself so dismally failed to reach - the issue is not one of the relevance, or otherwise, of the Morse Code, but the showing of sufficient dedication of putting in the necessary effort to get what you want. Going for an M3/CB Fools' Licence and then posting personal attacks in the way that Eric did is a sure sign of lack of such dedication.

Eric - you are a stupid boy and should grow up. It may well be that you wear long trousers but it is certain that your mind is still in nappies.

The Childish Broadcast (CB) quoted below would suggest that
the 2 letters, number, 2 letters format used by Britland CB
licences is also in use by Yankland in the KN6 series.....

Frank Dinger's Childish Broadcast (CB) serves to illustrate
well the Trojan Horse of the CBer-Masquerading-As-A-Radio-Ham
warned against by the OP.

Just ignore his outpouring - he is as irrelevant to _REAL_ Ham Radio
as is the RSCB.

You should be aware that
1. Common abuse is not libel.
2. Use of the word, "allegedly", however spelt, does not
give you a defence in a libel case.

> A single 4cx800 will get you close to the legal limit.

That's being over-ambitious. The manufacturer's data (Svetlana) says that a single 4CX800A "will conservatively produce 750 watts PEP SSB, and 750 watts Key Down CW in any of the three modes: grid-driven, grid-driven passive input, and cathode-driven."
http://www.g8wrb.org/data/Svetlana/pdf/4CX800A.pdf

You can certainly screw more power from the tube, but intermodulation levels will rise rapidly. When selecting a tube, a good rule of thumb is to expect an RF output equal to the tube's anode dissipation.

If the original aim was for something "in the region of" a kilowatt, it would be well worth considering a single 4CX800 at slightly reduced output.

But the Novice RAE is no more, and the comment applied to the RAE
as it existed at the time of the Novice RAE.

The comments are not revalidated for the 3-level farce fiasco that
exists today.

Ok, thanks Ken & Ian & others. My post has spawned just the type of comments that I had hoped for.

Ian, I've been over to Tom's tubes and I see you have boards over there. If I do the tetrode I will probably pick up a kit to help out. I don't like to re-invent unless there is a clear-cut advantage to doing another way. I'm up in the air over 2 stages or the Tetrode. I think the tetrode is probably going to win. I've posed the question to some AM types on AM Fone to see what they say.

I didn't have the data sheet in front of me, but I just assumed that
with a plate rating of 800w it would max out near 1200w out.
The 3cx800 tube will put out this much and there are single tube
amps using this bottle that will do that. Guess the 4cx800 is a
bit short on the plate voltage or max cathode current rating to
make it to 1200w.

Well you could use a pair of 4cx800's to get to 1500w out if that
is your goal. A pair of these are STILL cheaper than a single
4cx1000a or 8877 (especially with the cost of the sockets
figured in).

Hi Ken, I had a similar problem with an F455 XXXX 05 mechanical filter for a 75S-3B/C receiver. When I would switch it in, the insertion loss was 20 dB plus. Since I figured I had nothing to lose, I carefully took the filter apart, and as I recall, there are three wires that are spot welded to a row of resonating discs, and my filter had some busted connections on one row of the resonating discs. I knew I could not fix the filter, per say, but since I bought the 75S3-B from the original owner, he could have very well dropped the filter, and then installed it... I propose this for your filter. Since I haven't taken apart a R390A filter, plug the thing in, and see if there is any insertion loss. It may be that in your filter, which I presume is in a round package, like a 75A-4, was affixed on either end, where the input and output transformer(s) connect to the resonating discs, may have been held in place with some foam or glue to keep the discs from moving. I have seen in some Japanese mechanical filters they use a foam substance that degrades over the years, however, I'm not sure on the R390A filter.. So, plug the darn thing in a good working receiver, and see if it works.. If its busted, then you've only wasted a few minutes.. If your in dire straits, and need a new filter, or a used NOS filter, there are plenty out there.. BTW, I haven't known or heard of anyone that has really fixed a Collins Mechanical Filter with busted resonating discs where the stadia wire has broken loose from the discs... 5967. BF964S noise - alternatives??

Newsgroup: rec.radio.amateur.homebrew

Source record: 15349

I'm looking at getting a preamp that's based around a BF964S.

These appear to have about 1dB noise figure at 200mhz. It's to be used on 2m.

Does anyone know of a suitable alternative that I could swap it with that has less noise?

Sam

Thanks for the info.

This filter is from the R390a and is normally soldered into the circuit. It does not have terminals that can 'plug in', the filter is mounted under the chassis in a bulkhead that shields the input from the output. The unit I have came in the original Collins box and was sold as a spare. I have another Collins filter, I think the part number is FA455N27 that is the usual plug in package with three pins on each end, probably from an S line rig. This filter makes no internal sound when handled, so it is still in good shape. I was going to use one of them in a homebrew rig and the older R390 type has a 2.0khz bandwidth vs the 2.7khz bandwidth of the newer filter.

If these filters can go bad just sitting in the original box in a low humidity environment, I wonder how many R390A's now have rotting filters?

Too_Many_Tools wrote:

> Thanks for the responses so far....
>
> A few more questions....
>
> How much and what type of storage do you have?

seems there are pros and cons to all of them. Budget is a relevant question, you wont get tracked racks on a limited budget.

Cardboard boxes are budget-free, most flexible, spares store flat, and you can cut them up for sound proofing.

> How are the workbenches laid out most efficiently? L shaped? U shaped?
> T shaped?

I dont know. I've always gone for multilayered where possible. But whats best depends. Being able to put some kit on a half depth shelf under the worktop saves space. And another high shelf gives more opportunity for more gear thats semi within reach.

> How much stationary and how much mobile?

if theres room to move anything about, youre not using your space efficiently.

> What do you like for lighting?

Flourescent 3500K, 2 or 3 lights with switchbank so you can vary the level. High brightness is quite unpleasant all day, and gentler lighting no good for all work.
5w CFL inspection light. Ultrabright LED on the end of a foot of bellwire for a tiny spaces light inside equipment - very handy. Be sure to sleeve insulate it.
The one thing I've never found handy is an anglepoise. Too large, too uncooperative, too often in the way.
Magnifying light for sm work - though I dont have that here.

> Has anyone built power busses into your bench? If so, what was it?

On front of, side of, above, behind, under, yes, but not into. Into is too inflexible, and a pointless money spend imho. I used built-in at work but never thought it the best option.

> How about floor coverings? Ever drop a tiny screw or surface mount part
> on the floor and spend hours looking for it?

No, consider what the part costs and what your time's worth. There are normally more in the box. I always use a multicompartment tray to put removed bits in so this doesnt happen.

I suppose antistatic lino would be the ideal floor, but never had it. Ordinary vinyl floors are the worst for static, I'd avoid those. Concrete conducts more than I'd like, puts humans at risk. HT PSUs with reservoir caps are effectively not protected by RCDs (GFCIs). Wood is the best imho, its insulating, doesnt generate static, comfortable, smooth surfaced, looks good, feels good, is often already in place, is low cost, easy clean, low noise, what more could you want?

Dont overlook climate control. I dont know where you are but summer dryness isnt good for static. A wet towel and fan restores RH and catches pollen, if you dont want to spring for proper climate control. Also fumes can be an issue at times, esp burning plastic, though I've never considered going as far as a fume cupboard. Outdoors is fine for that occasional job. But if you really wanted everything, I guess a powerful extract fan at the back of the bench would see occasional use.

Dont forget to ask the cat too. You need somewhere comfortable and close for kitty, somewhere that keeps an obstacle in the way of climbing on the bench, so you get enough time to take action re soldering iron, voltages etc. In practice you need a few somewheres, and the cat will decide which is good. At least one within reach and one out of reach.

When you get on to test gear, definitely have 2 computers. One for the serious stuff, the other one you can put every bit of unknown but looks interesting software on you want, turn it into an all singing all dancing all crashing test centre. I never knew I needed a vector scope, but with a PC its free. Ditto a wide range of variable performance test gear.

this is what happens when you make a test instrument do what it isn't
supposed to.
Yes, what you actually measure is the interwinding capacitance pf the
coil. the bigger coils have quite a lot of it. besides, the capacitance
is not a linear function of size. there are so may factors influencing
it that you can't realy calculate it. like they say, your shoes size
and underwear color go into it.
but it's OK: thi is the way it's supposed to work.
I compared it with the Autek analyzer I laso have

I suggest that you learn something about computers - the
qsl web site was working well in the 5 minutes immediately before
I wrote my original post (the one that got lost).

And, on checking now, it is still working; I wouldn't follow
if the roles were reversed, but you
may like to try the following....

http://www.qsl.net/m5gwh/about%20me.htm

So, what happened? Did the infantile and aggressive persona
that you present to this NG result in you getting sacked as
someone being unsuitable to have contact with chidren?

Leigh Preece wrote:

I'm curious, what sorts of things do amateurs do that really need
better than a 1dB noise figure on 2 meters? I can understand it on
higher frequencies, but I'd have thought that galactic noise, at least,
would be a limiting factor on 2 meters.

Looking to be educated,

Tom

I don't believe that is correct.

What you are measuring is the net result of the interwinding capacitance PLUS the reactance of the coil, but it is only correct at the frequency of the test. Change the frequency and you will get a different answer. You are NOT measuring the interwinding capacitance alone.

I also question (a little) the need for better than a true 1dB NF
when using a terrestrial antenna in the 2M band. On the other hand,
if the transistor is speced to be able to supply 1dB NF, but isn't
working as well as desired because of preamp design, high return
loss, etc.

It isn't really HARD to get 1dB NF at frequencies
below 1GHz (or even higher), but it is sometimes tricky to get a good real
world NF while also providing good return losses (good impedance match),
at high signal levels, especially while trying to minimize DC power usage.

My own high-end jelly bean for near-ultimate performance below 1GHz,
moderately high power for reception (10mw - 100mw), reasonable noise match in
the 50-75Ohm range, but perhaps a little tricky due to high frequency
behavior would be the HP f54143 (Hi IP3, reasonable noise match, it has
lots/too much of UHF or higher freq gain, but is moderately well behaved).
This part costs less than $2... (I bought my supply for between
$1.50 and $2.00 each.) I'd also consider using moderate current SiGe
transistors while biasing them at about 10ma to 20ma (which is generally a
reasonable range for a good 50-75ohm noise match.) Either the SiGe
transistors NESG2101 or the PHEMT (54143) will give better than 1dB NF
with a generally fairly wide noise match. (SiGe is generally better than
most alternatives for oscillators -- off subject -- also, due to their
generally very good 1/f characteristics and generally high Beta, which
translates to generally low current noise -- esp in the low freqs where
part of the AM/PM noise comes from.)

Given the very wide signal strength range, I'd definitely consider OIP3
of at least 25-30dBm, and try to design for no more than 10-15dB gain.
It is very possible that even a very highly performing preamp will work
worse than no preamp at all!!!

John

I insist that it is simply a page - maybe you should learn the rudiments of website assembly as there is no identifiable index or homepage but a collection of orpan pages or what would have been 'parent/child' pages.

Yes - correct - but again this is a directory listing and not a website as, I state above, a website requires a definate 'index' or 'home' page.

> I suggest that you learn something about computers.

I suggest you learn something about website construction and the heirarchy system of website structure.

I partially agree, Bill. After looking at the schematic and crunching
some numbers I see that the added inductance at the 750 kc test freq
would have the equivalent 'shift' of about 20pf in this particular example.
So taking that into account there's no reason to believe that the
remainder of the reading is not the actual capacitance inherent in the coil.

One reason for attempting to get a low noise figure as possible, even for terrestrial working, is that you can then afford a larger loss due to input band-pass filtering.

The unloaded Q to loaded Q ratio of the input filter determines the filter loss and the unloaded Q is mainly defined by the filter construction (LC, Helical, 1/4 lines etc.). A 15:1 ratio would give about 0.5 dB loss, while 5:1 ratio attenuates the passband by 1.5 dB.

Assuming a unloaded Q of 100 for an LC filter and loaded Q of 20 would produce a 7 MHz bandwidth (at -3 dB points) with 1.5 dB loss in the middle of passband and assuming 0.5 dB preamplifier noise would give a total 2.0 dB noise figure, with a nice attenuation of broadcast FM and VHF TV signals that otherwise might overload the preamplifier.

A high-voltage optocoupler; cool.

I've posted a schematic for a hv opamp (400 v p-p) that uses two
optoisolators as the output push-pull stage... it's very cheap and
simple. A higher-voltage photodetector, like a glass power diode,
sounds useful, too.

I worked once with a company in Southern California that had a neat
gadget: it was a truncated cone of silicon with gold contacts on the
base and the flattened apex. It would stand off something like 5KV
until you whacked it from above with a laser, illuminating all the
sides of the cone, whence it would conduct hard. I think they went out
of business, though; it was pretty obscure.

I take what they give me- but I prefer those big roll around
multi-drawer jobs with each drawer user partitioned.

>
> How are the workbenches laid out most efficiently? L shaped? U shaped?
> T shaped?

Makes no difference- all lined up against one wall works well, the
mobile stuff needs to go in a rack anyway- roll the rack to where it's
needed, some people prefer carts.

>
> How much stationary and how much mobile?

Every thing goes mobile at one point or any other. Stationary just means
it will be something to make mobile later.

>
> What do you like for lighting?

It can only be flourescent- and built in to the bench in addition to
normal room lighting works best.

>
> Has anyone built power busses into your bench? If so, what was it?

A real bench has bussed line voltage with *LOTS* of receptacles.

>
> How about floor coverings? Ever drop a tiny screw or surface mount part
> on the floor and spend hours looking for it?

It always has to be thick insulating mats rated for 20KV, any IC dropped
on the floor is considered lost and not used, a screw is a different
matter, you shouldn't have to hunt for a hard to find screw, you should
be able to cut to length any replacement.

Better make space for lots of data books and a computer, fire
extinguisher, metal working machines, first aid kit, smoke alarm,
set-aside projects, file cabinets, and nice-to-get-to-later junk you
will accumulate. And make it so that every damned thing can be locked
up- especially the door to the lab, and more locks on all the storage
cabintes once inside, you may consider touch pad enable of all the room

receptacles, and installing an alarm.

I'd call these guys up (http://www.radiomanrepair.com/) and see if
they'll provide a quote for repair of the OEM radio. You'll have a
neat, operating vintage car radio, and you might even get the cash back
when you sell the car.

It isn't trivial to convert FM broadcast signals for reception in the AM
band. You pretty much need a back-to-back FM receiver and an AM
transmitter to do that, and the RF work associated with homebrewing a
converter would (honestly) place the task out of reach for anyone who
needs to ask how to do it. :-)

Same trick I used when I moved my parts cabinets from PA back to IL in
1980s.

Finally gave away my last old AkroMills metal cabinet (50 drawer) to new
amateur earlier this year.

They used to sell FM to AM converters for car radios. They 'worked' ok.
Watch ebay for Audiovox FM Converter. Here's one example.
http://cgi.ebay.com/ebaymotors/ws/eBayISAPI.dll?ViewItem&item=4597467612

Regular old used ones generally sell for $15-20.

If it were me I'd get the original fixed, though.

Source record: 15389

Hi Ken,

1500w was the target, but I see it's not so easy a target to hit on a budget. I just did an inventory of shack and realized that I spent a whole bunch of cash over three years just getting back into radio. A couple of boatanchors, high performance receivers and some decent test gear have kept the accounts payable department busy here in MA. (The N9 call followed me east after college) Wife and I have other interests that also run on cash, so I can tone down the amplifier performance a bit no problem. I can be happy with a smaller amplifier and maybe some time down the road build a bigger beast. 100w-200w of carrier on 160-40 would suit me fine right now. I can build giant multi-kilowatt transmitters using mosfets if I want to, but the tube thing has a certain appeal to me now. I got my first class commercial ticket over thirty years ago but never did much with the hollow state. I'm having a blast now with the BAs.

Thanks for the help (to all). I'll be asking lots of questions as the design goes forward.

There are guys out there that will take your radio and stick new guts
in it. You end up with a radio that looks completely stock 1969
Porsche, but performs like a brand new Mark Levinson.

regards,
Bob

Looking for a specification of the HP 11953A termination resistor (BNC).
Measurements of two different units indicate R=51,3 Ohms.
I would have expected something closer to 50 Ohm.

Yes, the ohmmeter is calibrated...

I've got a few 1N4003 and 1N4004 diodes with all-glass packages but I'm not sure how recent they are. They have the (older?) Fairchild logo of an italicized "F" with the middle stroke extending on both sides of the vertical. I'm about 90% sure these came in one of those "20 rectifiers for $2" packages from Rat Shock, so who knows how old they really are. The bodies are about 2.5 mm diameter by 4 mm long. Inside the glass, the ends near the leads are orange, with a clear strip less than 0.5 mm wide near the middle.

Testing them with the "diode check" on a $40 multimeter and either a 40 watt clear globe lamp or a TV remote control doesn't show much photoconductivity, but I suspect I would need to look a little harder than this to see it.

Or use a differnt diode in a glass case. The PN junction makes a
decent small area photovoltaic cell (transistors too).

FYI: if your using 1n4007 for a varactor, light impinging on glass
versions will drive you nuts (Florescents will give AC hum
modulation) and lower the Q.

Allison

I need about 20 more, but they don't make them anymore. I've been
using the crappy all plastic ones that shrink and jam. I'm about to the
point of putting the parts in plastic bags and driving over the damn
cheap plastic things.

How many do you need, and can you use ones pulled from PC boards? I
may have some left that I pulled from damaged boards.

Travesty.

Please preserve the radio in its original condition. FM radios are
common as dirt but a 1969 Blaupunkt is a collector's item.

Germanium diodes like a 1N34 in glass case are quite light sensitive.
Some LED's are too and IR emitter LED's are quite sensitive to IR.

Bill,

A reliable way to find the effective shunt capacitance is to observe the self-resonant frequency of the coil. If it's really about 25pF, and the coil really is about 5mH, I'd expect self-resonance at about 450kHz. Can you make some simple measurement of the self resonance? (e.g., square wave coupled loosely to the coil; scope monitoring the ringing. Or signal generator swept across the suspected frequency range, looking for a peak in the response. Key is to couple the generator and the detector to the coil loosely.)

Cheers,
Tom

==========

What is the uncertainty of your ohm meter ? If it is a DVM then apart from the uncertainty the actual value is plus/minus 1 of the least significant digit.
You really have to define 'Ohm meter is calibrated'

> as I rotated it in my hand I could feel something
> inside shifting back and forth.

The inside has the resonating elements "suspended" in foam. The foam does decay, but usually in place.

Check the resistance on each side of the filter, it should be something like 50K ohms. If either one is open circuit, the tiny wires that connect to the coils inside have probably broken. Check the R-390A sites, some have taken off the end of the filter can and shown pictures of the inside, and some have even reconnected broken wires and at least thought about replacing the decaying foam.

The 4kc filter is the hardest to find but not impossible (either demand or most used/most quickly worn out), the 2kc filter ought to be easier.

Tim.

There is quite a large market for Porsche parts, even for older cars. There is also quite a wide range of prices so it pays to look around.

I had the radio die in my '98 Boxster. It looked to be about $500 to repair it, and a replacement was over $1200, over 700 for a rebuilt radio. Now, it was a nice radio, but $1200!!

After much hand wringing and looking around I finally found a speed shop halfway across the country that had a rebuilt radio for around $200. There are literally hundreds of Porsche blogs and mod sites on the net; many of these can provide leads. Don't forget the obvious Porsche suppliers and, of course, eBay. Even if they don't directly have what you want, often they can provide clues.

Back then those radios weren't that great, and a LOT of people yanked them in favor of radios with cassette players or, later, CD's. Porsches tend to be driven for a LONG time. So the odds of finding a replacement for a decent price might be pretty good. Heck, I may have one of about that vintage lying around here. Not much chance of ever finding it in this shack, though!

As far as making a converter, I don't hold it to be quite as tough as some of the other posters have indicated, but it could be a real barrier if you aren't already a homebrewer. The fact that you are posting to a ham radio newsgroup leads me to suspect you might not be a total innocent around a soldering iron. There are a number of chips, NE612, 614, 615, that contain a large fraction of an FM reciever. If you only want one station, it is actually pretty simple. Building a high frequency VFO, though, is a bit of a challenge. Modern synthesizer chips can greatly ease that, but they are all little bitty surface mount parts, and you gotta program a computer chip to drive them. Really not all that insurmountable, but it's not an afternoon project, either!

Might not be such a bad plan to run down to Best Buy or whatever and get a cheap replacement; pretty good radios are cheap enough that it could be temporary. Then you have tunes while you are getting the real radio fixed.

..

You know, I agree in principle that Ham Radio is being so dumbed down that it no longer can be considered a technical hobby. (But then all of education has been dumbed down. It is more important to assure a student's "self-esteem" remains intact, than that he learn the subject).

What amazes me is that every time this "faq" is sent to the newsgroups, the same idiots respond to it, and get into a flame war. When it dies down, it only requires the repeat of the same message to get the same idiots stirred up again.

Sort of a Pavlovian response. I guess for some, it might be fun to watch dumb animals drool. Maybe it's a UK thing......

The thing you need to bear in mind is that of the current 55 messages
in that thread, no less than 23 - not far short of half of the total -
were in fact posted by the OP. Some of these involve him posting - or
barking - replies to himself. I wasn't aware that Pavlov had trained
his dogs to drool at their own barking. But the chap concerned claims
a qualification in psychology, so perhaps he could name this
phenomenon for us.

The Wise Ones live in the depths of the D, E, and F-Layers, and in the servers at Yahoogroups.com. They are the descendants of the Gods. I personally subscribe to the theory they are the children of Thor Heyerdahl, the Viking god of Thunder and Balsawood Raft Dxpeditions. But that's another story.

The Wise Ones criticize everything that happens on the air and on this list, but they can't police every pileup or every Yahoogroup by themselves, so every morning, just before daylight over Katmandu, the Wise Ones select the "Mostest Intellegentest Ham Ever" in their layer and convey upon him the title INFLICTOR OF HIGHER MORAL HARANGUES. This title and its duties last until the following dawn on Bouvet, if someone is there to observe the sunrise. Otherwise your duties end when Riley Hollingsworth gets tired of your crap and sends his lawyers with a gag order.

If you are ever chosen you will know because a representative of the Wise Ones will anoint your temples with oil from a forty year old bottle of Dr. Guano, collected on Ocean Island by VR1L in 1963. For that day you will be known as The Chosen. Your duties will be to seek out those that don't do things the way you do them (in other words, the right way.) When you find them, it will be your duty to correct them.

Think about all the ills of ham radio that you can police .....too wide, too weak, too slow, too fast, what's your call dammit, wrong VFO, rotten fist, QRQ, QRS, poor pileup control, wrong band, wrong QSL route, you timed out the repeater, wrong lingo, not enough green stamps, you're in the DX window, no-coders not allowed, coders suck, ... these and many other sins are all your to root out and expose!!!

When you find these wayward ones, you will lumber onto their frequency, stand up in your operating chair and shout, I AM A BETTER HAM THAN YOU, SHUT UP AND LISTEN. You will now have the wayward one's undivided attention. He will think about this very briefly, then yield to your superior intellect and ham skill. He will be very receptive to your thoughts and point of view.

Lecture him and proceed to the next wrong doer.

Now for the sad part of this tale. There are pretenders and charlatans out there who try to usurp the rightful powers of The Chosen. To you villainous few, I say beware. The Wise Ones also created BAWA (Baddest Ass Whats Around). No matter how bad you are, BAWA has the ability to be badder. You will know when you start your lecture and Bawa yells back, "You're a jerk, but I'm a bigger one. LET'S ESCALATE".

And you will have no choice.

But soon BAWA will tire of you and sink your little balsa boat. As you slip under the surface you will yell, "BUT I WAS RIGHT, DAMMIT" and you will once again prove the ancient mariners axiom -- AN OPEN MOUTH TAKES ON WATER.

Hans,
You've missed the point which is that we are in a privileged
position as the result of our educational achievements. Allowing the
standard represented by those achievements to fall such
that turnip-brained CBers are perceived as our fellows is
the route to Company-Built (CB) rigs only, and our hard-earned
right to build our own gear will be lost.

It's not a question of snobbery, but one of preserving the
world of _REAL_ Ham Radio.

Still looking for a Tripp Lite PR-25 (or similar model) DC power supply
schematic to repair the club's repeater power supply. If any one has one
I'd appreciate a copy, email or otherwise.

I called Tripp Lite just now. According to Technical Support their
PRESIDENT has
recently mandated that they would NOT send any more schematics out.
However, I could trade the supply in for a new one at about 85 bucks.

Thanks and merry Christmas,
Paul.

Seeing as how you are a "packer fan" I may have just what you are looking for. I have one of those FM to AM converters. Got it sometime in the 70's. It is a very small box about 3/4 inch high by about 4 x 6 inches. Used it in a car that came with only an AM radio. Just plugs into the antenna jack and the car antenna plugs into it. Needs to also hook to 12 volt power. Push the button and it switches the converter in line. Set a push button on the am radio the the output frequency of the converter and tune in your FM station with the knob on the converter. It is mono FM though. No stereo. Works great. Email me at garyschafer@comcast.net if interested.

There used to be all transistor converters like that back when. Now
that I think of it there might even be one in the garage here. I'm not
sure though, but the last time I was clearing room for the car I
vaguely recall coming across such an FM converter on a shelf. Would it
be something you might want if it works?

Paul -

IF it uses the standard LM723 IC regulator and pass transistors (2N3055,
2N3771, or 2N3772) you do not need a schematic per say - to repair. Check
the pass transistors with you trusty VOM/DVM .. can replace 723 !!

Here is the DIY web site for linear supplies

I think Akro-Mills still does, but they don't sell them through consumer
outlets. Try Applied Industrial Technology (ie. Maintenance America).

There are a couple of smoked resistors on the regulator board. I can not trust the ohm meter reading so I wanted to verify its value. I am trying to avoid De-engineering the board. Now once the resistors are replace there may be something else that smoked the resistors too.

Paul.

Maybe so, but this wasn't a GTO, it was a bulk-effect device,
blindingly fast.

Can an opto-triggered GTO be turned *off* with light?

Thanks NT....I appreciate your detailed response....very helpful.

Anyone else?

How about arrangement of test equiptment? I have seen many benchs
overtaken by stacks of equipment with it running over on the floor.

TMT

I have several benches, with each set up a different type of work.

Though it creates static hell IME. I much prefer wood, it will insulate personnel from anything too nasty, but without the static. (avoid nailing wood to concrete, which conducts.) With floor insulation you have to keep fondling the benches as you walk along, else you build up enough static to get bit just from crossing the room. A real hallmark of poor design imho, yet seems to be industry standard here, including in labs working on ESD sensitive kit.

I guess antistatic mat or coating on the bench goes without saying. Not needed for metal benches, but they have their own risks. Coating beats mat imho. Mats warp, catch on an elbow, dont fit perfectly, deteriorate, etc.

> any IC dropped

> extinguisher,

I might make that extinguishers (along the escape route), getting out of a stuff packed room in a fire can be no joke. If you're going for the have everything approach there's always heat activated sprinklers. Just dont make the mistake of using those extinguishers to save your stuff when you could be getting out. Your exit must _always_ be clear, the moment its threatened get out immediately. I'm told fire extinguishers are liable to kill more than save otherwise.

BTW put emergency lighting near the floor, not up high as is usually done. When high up, by the time the light gets to the floor where youre crawling out, its all been absorbed by the smoke. Put it at exit(s) so when you dont know whats going on or where you are - disorientation is a very common problem in fires - you can just crawl toward the light. If youre working in a detached wood shack, an axe by the bench that wil bust through the wall.

> metal working machines,

Yeah. If there are no limits, you might want one of those 3d laser
gloop prototype making things. I forget the name but the computer scans
the beams through a tank of gel, and a hard plastic prototype is born.
Very pricey iirc, but sometimes worth it.

A runner is handy. If you need something you dont have, just call them
and they show
up with it in 30 minutes etc. This is something thats not so hard to
set up, as long as youre not in the middle of nowhere.

> first aid kit,

If its your own shack, tools of self defence too. Not just weapons, but
lighting, recording kit, etc. I've found recording kit pays for itself
with ease.

> smoke alarm,

make that 2.

> set-aside projects,

sheet wood that fits on the desktop. Put a sheet on before starting
work, ad you can lift your whole project onto another shelf any time,
and use the bench for another task. Multitasking.

Almost forgot, replace notepad with win32pad. Its the bees knees for
information libraries. You can have 50 files open at once no problem,
they open instantly, .txt format is (and more importantly will remain)
100% compatible, and so on.

> file cabinets, and nice-to-get-to-later junk you
> will accumulate. And make it so that every damned thing can be locked
> up- especially the door to the lab, and more locks on all the storage
> cabintes once inside, you may consider touch pad enable of all the room
> receptacles, and installing an alarm.

This is a good point, security. I like to modify locks, it makes almost
all lock pickers unable to pick them. Lock pickers are mostly not that
skiled today.

Its yet another advantage of cardboard boxes on wood shelving, makes it
looks like a downmarket shack filled with junk. May not look flash, but
it means you get to keep it. Probably more useful for self contained
unguarded units than corporate workshops.

A PIR alarm linked to a _very_ loud noise is all it takes to scare a
lot of burglars away. By loud I mean LLOOUUDD. Its funny watching the
video afterwards too :)

Almost forgot, any workshop needs a sink, and many dont have them. And
a microwave/fan combi oven. And everything else that enables you to
keep working comfortably.

I've never solved that one, just have to move the stuff each time. But it reminds me of one thing: some kind of easily portable testkit would be very handy. One day I had no multimeter for some reason, and ended up using 3 light bulbs to measure V and i. It worked, got it sorted out, but is a situation one should not be landed in.

Ah, also a set of cheapo backup tools in the car. The finest tools dont work when theyre left behind, lost, stolen etc. You can only keep cheapskate tools in the car, anything better and they get nicked. Proved useful several times.

Do you have to be able to see the surface of the bench?
Mines about 20' long X 3' deep and there is very little surface
showing.

>
>What has worked for you?...what hasn't?

What worked? Let the chips fall where they may, don't more anything.
What didn't? Trying to keep a neat and clean bench.

It's because I've got about 3dB of aerial loss and filtering loss, that I can't get rid of.

But thanks for the advice on the devices, I'll take a look at them and see if they would substitute, and how I would need to modify the circuit if not.

Sam

6069. If the answer's, "M3", it must be a bloody silly question!

A joke for the Winter Solstice season, largely known
as "Christmas" because the Christians have shown their
true mettle over the years by burning at the stake those
who opposed them, and yet who have parasitised so
much of their opponents' beliefs such as Yule Logs,
Holly, Ivy, sacred sites and the choice of this time to
year, all as a means of insidious propaganda.

What a truly nasty sect are the Christians! (They even
went so far as to torture those who claimed to be
Christian but who objected to rule from
Rome, seeming to lose sight of the fact that the origins are
not in Rome but in Palestinianstan!)

If the Christian god really exists, then he must have a pretty
sick sense of humour - sending that Tsunami last Boxing
Day. He must also be pretty thick - in an age that has
encompassed the postal service, carrier pigeons, heliographs,
semaphore, telegraphy, telephones, radio, television, GSM,
GPS, Satellite TV, and the Internet - when he wants to
communicate with humanity he sends a tsunami? That God
seems as thick as those who believe in him!

Anyway, to keep this on topic, taking the lead from
the title of the thread.....

Q. If the answer is, "Cockrobin", what is the question?

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B
licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

I don't celebrate and have withdrawn from the prezzie cycle
for some years because it's a most difficult time for alcoholics
and the time of year when one is most likely to have a "slip"
(as it is termed in AA) if one is not on one's guard all the time.

However, as I have to find humour from within myself and not
rely on some external drug, on the occasions when I do
go to social gatherings, I am accused of being the drunkest
person present!

So, alcoholism has one big advantage - I don't pay out loads
of shekels to give to other people loads of things they don't
really want and get in return loads of things that I don't
really want! The spare cash that I have goes to the
purchase of components that I do want!

PS.There's a new condom on the market this Christmas, the
"Sant Claus" model.

It's 6 foot long!

Why? Because he only "comes" once a year, and when he
does, he fills up your stockings!

My personal reasonal reasons for celebrating Christmas is to look back and on my previous 12 months achievements, also to take time out from a busy work schedule (the aerospace industry doesn't run itself you know!!) and spend time amongst friends and family. Even exchanging gifts as a token of appreciation for being there thru the ups and downs of the past year and to look forward to whatever the future holds. A beer here, a spirit there and the odd mince pie does no harm.Indeed, a wondorous time for even the strongest disbelievers!

....and a good excused to get pissed for a week and a bit!!!

don't even try!
the ambient noise levels on 2m are such that even a 5 to 6 dB noise
figure won't limit your MDS.
it's just going to complicate your life, because the amplifioers able
to provide a lower than 1 dB NF tend to become unstable. the trouble
isn't worth it.
Saandy 4Z5KS

And an interesting revelation recently was that the
red-coated Daddy Xmas isn't traditional (He was
originally GREEN, and an extension of the Celt's
interest in the evergreen trees, those that did not die
and that therefore were immortal).

The red colouring ("coloring" for the benefit of
the unchristian warmongers of Yankland) came
about as a Coca Cola advert!

I must take you up on that slur, for you seem to
have misunderstood, (perhaps deliberately?) what
is being said.

There is no hate whatsoever in welcoming with
open arms all those who wish to be part of the
technical pursuit that is Ham Radio.

There is no hate in setting ourselves apart from
those who are not Radio Hams in an effort to
preserve our hard-earned rights.

There is no hate in correcting those who have been
misled by some desperate Billies-No-Mates to think
that they are Radio Hams, when, in fact, they are nothing
of the kind!

No. There is no hate whatsoever in what I publish; merely
a statement of who we are, and encouragement to exert
themselves to those who would join us!

NWTAP, but his postings are more symptomatic of bipolar disorder than
of senile dementure.

Focused rage at the new licensing scheme, misdirected rantings at the
new licensees who are merely progressing through the licensing régime
as it now stands --- mixed with a manic fixation that everybody else in
the UK shares his rage, and that he alone can fix it by repetitive
posting of the same tedious drivel umpteen times a week. The other
fixation with (as he puts it) "kiddie fiddlers" is indicative of the
heightened libido often associated with manic depression.

In any case, if Wiltshire Primary Healthcare Trust can't afford the
frontal lobotamy and 4 rolls of double-thickness rubber wallpaper that
he so desparately needs, they certainly can't afford thioridazine.

For some reason, this brings to mind one of todays Top Nooz stories -
some woman who was jogging in the park was jumped by some guy who
wanted to assault her and she kicked the shit out of him. But they
noted that she was 6' and about 140#, and he was 5'6", 120#. It
was actually kinda refreshing to hear about someone defending herself,
but how stoopid do you have to be to attack somebody that's twice
your size? ?:-/

Cheers!
Rich

Holly Crap!!! You have anyplace I can get a pick-up truck load of money
for all these
suggestions? LOL

I like to build me a "play with my radio toys" bench not a do everything
Electronics Lab.
Some nice suggestions, but waaaay out of the average Hams pocket book I
thinks.

May need to plan what it is you really want the bench for. You could spend
the rest
of your life putting it all together and not enjoying the things you want to
play with.
After all, if you look at the ARRL Handbook; it would be nearly impossible
to have
one workbench to fit all aspects of Ham Radio. From QRP to Satellite..
Wheeew!
what a spread. Better think about it for a while first. Remember it's not
the one with
the most toys that wins.... It's the one who gets to play the most with
their toys.

Keep the ideas coming though, might be a few good ones I can afford on my SS
check. :-)

No suggestions for the apartment size cooler for the beer and a chair for
the visiting novice?
Er better make that a recliner.... some of my stories take a while. ie.
Rag Chew Award
Then there was the time......

I like wood benches for some of the same reasons.
I have been using a rubber static relief mat, that holds up
under high heat, and also has a natural curl, so parts
always settle back inside the mat, and not roll away.
This thing is great. I doubt if MCM still has a similar item.
The stock number on the mat is not currently valid.

I've been using color printers
more lately, for laying out various things, either building things
or fixing things. Having a circuit board, you can take pictures of both
sides, then flip one side, and you can more easily trouble shoot or
build things. Having a color laserprinter makes the process faster.

Having multiple benches is almost mandatory for certain projects.
I frequently use a Rubbermaid cart to put equipment on, and
work right there on the cart. You can always push the cart away, and
work on something else. Its also necessary sometimes for big
or heavy objects, even dripping things like water baths. Screws, etc.,

stay inside the carts tray.

A very bright flashlight held along the floor, will usually find parts much more easily than just looking around.

At home I have had "workbenches". but my number one work bench, was the top of a washing machine. Its a bitch when the screws fall inside.

You're right, of course. It was unprofessional to attempt a remote
diagnosis. Besides, a face-to-face consultation would be fascinating -
there must be enough material there for an entire conference.

Paul -

Where are these resistors .. the typical linear supply has low ohm
equalizing resistors across the NPN pass transistors .. and only a few in
the regulation circuit off the LM723 pins .. for example a 1 K is usually
used from pin 4 to the voltage adjustment potentiometer.

gb

Here's a link to an Astron supply:
http://www.seits.org/features/pwrsup.htm

Assuming a typical 723 ==> pass transistors linear supply,
it shouldn't be hard to figure out the values of the cooked
resistors. The schematic at the link above serves well as a
model for many (most?) of that type of supply. Combined
with the LM723 datasheet, you can fix it.

It would be difficult, because no two home electronics workbenches
have the equipment or tools. That is why i have several benches,
including a couple extra that are stacked up in the corner for the next
time I get a batch of test equipment.

Having done some home hobby work in radio-electronics for, oh,
about 58 years give-or-take, I'll suggest some basics:

1. The Bench itself:

1.1 A possibility is the "butcher block" slab top, usually
made for an island in a kitchen. Finished or unfinished,
it can have your choice of legs added, attach shelves
above it, all fastened into the wood. Various sizes
are available, depends on supplier.*

1.2 Use a solid-core wood door blank with choice of legs.
Lumberyards carry those. Solid-core doors allow
fasteners any place along the surface. Avoid the
standard or hollow-core types. I gave a friend the
door I had (covered in celotex glued on) for model
aircraft building; he still does giant-scale R/C
still using balsa construction. No warping in it yet.

1.3 1-inch thick 7-ply (minimum) plywood can be had at
lumberyards and, for a slight extra fee, cut to size
you specify. Depending on size of lumber yard, can be
had with your choice of surface veneer, "finish one
side" (cheaper) or "finish both sides."

2. Bench superstructures:

2.1 Test equipment shelving or support for stacked parts
bins can be done from do-it-yourself wall-mounting
shelf units, bracket-mounted to rear of bench top.

2.2 Wall-standard shelving can have its standards mounted
on a slab of plywood (3/4" minimum suggested) attached
to back of bench top, shelves bought ready-made in
modular sizes.** Limited shelf depth to about 12"

maximum for modular shelving. Can also use plywood
cut to order but will seldom find standard brackets
to hold shelving deeper than 14".

3. A place to sit:

"Task chairs" such as are found at sales times at
Office Depot or Office Max, those usually adjustable for
height desired of bench top above floor. Various choices
of upholstery; plastic suggested to avoid solder splashes
sticking to woven fabric. Sales time prices around $40.

4. Convenient Parts/Tools Storage

4.1 Home storage containers with clear sides for visibility,
available from 10" widths to 18" widths (from Sterilite)
and are found in some food supermarkets for an average
of about $13 (Ralphs Markets in southern California).

4.2 Akro-Mills small parts cabinets. Three sizes available
now, all-plastic but sturdy. [they have a website too]
I have four of those in my workshop now, easily screwed
to a back wall of particle board and they have been
holding about 150 pounds of stuff for a couple years.
Price and availability is, unfortunately variable. I
saw mine first at an OSH sale, grabbed them while there.

* IKEA has lots of individual pieces for sale so their full
catalog is needed for detailed sizes. Six years ago I made
twin computer benches out of IKEA butcher-block kitchen tops,
using their legs for tables, added keyboard slide-out trays
using slides from Home Depot. The butcher-block tops finished
very nicely using just thinned sanding sealer but they come
very flat and can take cementing-on of melamine laminate if
that is preferred. IKEA has a website with most size details.

** OSH = Orchard Supply Hardware, a do-it-yourself store that is
in the southern California region. Their website isn't a
catalog but they do offer some do-it-yourself project ideas.
Lowe's or Home Depot have the same but the product lines they
carry are seldom complete...they tend towards certain sizes
of their products and product models (same for OSH). I do
know the local OSH has a good line of wall shelving; that
enabled me to build 39 lineal feet of book shelving on one
wall of our office at home.

Luckier than most home owners, I had a 13' x 13' center room to
play with, subdivided that in half, using "my" half for the
center workshop, making false walls and cabinets as well as the
bench itself (3/4" ply on 2" x 2" framing supports). Do NOT use
any vinyl top material as I did...it tends to hold solder
splashings and still reacts with masking tape (all-around-use
temporary fastener) adhesive. Avoid paint for the bench top

(useless in the long run). Bare wood okay and, if it gets too dirty, just use an orbital sander on it to take off the worst. Use good lighting. I have two double 4-foot flourescent units as the main lights, a "fill" light without hot spots. I had two long AC outlet strips but those managed to corrode inside and go phut. Surge-protected 6 to 8 outlet strips are all over the stores now at less than $10 each (I got a half dozen at $5 each on a local sale). Be alert. Bargains happen! :-)

Using up a pad of paper in planning is a good idea. I like 1/8" "quadrille" pads and do simple drawings in scale (for big things) to get the arrangements and sizes right. For benches, plan the heights that suit you, not the "traditional" heights which might have suited an old production shop. That and sizes available from vendors lets me plan fairly well the overall costs.

There was an email message from you in my inbox this morning.

It was deleted unread.

I do not accept email messages arising from NG discourse. If you
have an issue arising from matters in this NG, then this NG
is the place to discuss it, all open and above board.

The only reason for having the email account is because it is
a requirement of google groups. The mailbox does not get
accessed for days at a time.

If you wish to be for ever perceived to be a Childish Broadcaster
(CBer)
then carry on, as you do below, with your Childish Broadcasting (CB).

Not only is it unprofessional but it is also a criminal act for
a ship's radio "officer" to attempt to pass himself off as a
medical professional.

Grow up, Mike Gathergood!

Stupid boy.

6122. FAQ - revised version

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-22 08:47:32 UTC
From: Pierian Spring <radio.ham@lycos.co.uk>

In case their are those who get a CB-type rig such as the 817
in their stockings and are misled by those-who-ought-to-know-better
into thinking that they are Radio Hams, the weekly (and
revised) FAQ is posted a couple of days early to enable
the parents to take the CB gear back to the shop.....

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal

of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One such CB type is the so-called "Not-Ham". Otherwise
known as the CBer-Masquerading-As-A-Radio-Ham, this type
had their background in the hobby that is CB Radio and not
in the technical pursuits that lead up to a coveted Ham licence.
Easily recognised by their boasts of the criminal activity of
11 metre SSB operation, one wonders why they don't go back to
the CB Bands if such bands are dearer in their hearts than are the Ham
Bands? No _REAL Radio Hams associate with those who made an
illegal installation of transmitting equipment before being
in possession of an appropriate licence.

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham

could also hold a CB licence safe in the knowledge that such a licence says no more about him than having a land-line telephone, whilst continuing to regard Ham Radio as a separate technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between a Ham Radio licence and a CB Radio licence. To him, they are sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then tries to classify himself as the equal of the Radio Ham when, in fact, he is nothing of the kind. A sure sign of a CB Radio hobbyist is if he holds, or has ever held, a licence issued under the gangrenous degeneration that is the M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of Radio Hams but who are in reality nothing more than an apology for the failure of a CBer are those class B licensees who falsely proclaimed that they were against the use of a Morse Test to control access to the HF bands, until, that is, a test was introduced at their intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to enable them to handle even the simplest algebraic manipulation for Ohm's Law and thus, the disgraceful Class Ber's in the aforementioned category are not Radio Hams by any stretch of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds, or has ever held, a licence issued under the gangrenous degeneration that is the M3/CB Fools' Licence scheme!

SOLDERSMOKE!
A SHOW FOR ELECTRONICS HOMEBREWERS!
http://www.ourmedia.org/node/123300

Topics discussed in SolderSmoke 11:
Video of Trivial Electric Motor. Solar powered station on 80 meters. Mike's new PIC-pong game. Coax traps for a 160 meter antenna. Understanding solid state amplifier design. Homebrew shows on the Discovery RealTime Channel. The G-QRP Superdrug radio project. Altoids and I-pods. Listen at: http://www.ourmedia.org/node/123300

Background:
Tired of listening to Led Zepplin or NPR on your I-Pod? Wouldn't you like to be able to carry with you the kinds of ham radio conversations that you listen to while in your radio shack?
Mike, KL7R, in Juneau, Alaska, and Bill, M0HBR, in London, England meet regularly on the ECHOLINK system to discuss their homebrew radio projects. We are making them available as PODCASTS.

You can subscribe to the program, have them downloaded to your MP-3 player, and listen to them at your convenience. To subscribe, just cut and paste this URL into your I-poder (or similar) software.

http://www.ourmedia.org/mediarss/user/36170

If you don't have an MP3 player you can just go to the site below and listen to the latest program (and earlier editions) using the audio software on your computer.

http://www.ourmedia.org/node/123300

We hope you enjoy the program. Please send us feedback.

If you wish to be henceforth perceived as a Childish Broadcaster (CBer)
then carry right on with the Childish Broadcasting (CB) such as
you utter below.

You seem to be obsessed with me, you are chanting your
infantile playground tirades at every turn. Brian Reay says that
such obsession is a sign of envy. Have you no life of your own?

All _REAL_ Radio Hams have a number of ongoing projects
simultaneously. Some are held up for lack of components, some
for a lack of time, others for lack of info.
I wouldn't recommend anyone whose background
is in transistorised QRP to tackle the neutralising of a compact
PA stage with 600 VDC on the anodes after replacing the
antenna coupling capacitor unadvisedly, lightly, or wantonly. The
project
was held up awaiting info, and when I needed the space, was
one of a number that I disposed of. ISTR that an R1475 awaiting
restoration
also was disposed of at the same time. The project was underway,
I was fully prepared to have a go, in sharp contrast to the
CBers-Masquerading-As-Radio-Hams of today who buy their
goods from a shop and return them to a shop if needing repair.

You really do seem anxious to score some pathetic and childish
points. You may feel at home starting and then desperately
trying to continue a pissing-in-the-playground
competition, but that is not my style.

You do yourself, this NG, and Ham Radio in general no service
by discouraging the discussion of what we do and the problems
we encounter along the way if you pick up on minor points out
of context and sneer and chant from the sidelines. How are
we to encourage the novitiate other than by discussing what
we do?

Shame on you.

Grow up, Mike Gathergood!

Stupid boy.

I don't follow web links - if you have something valid
to contribute to a discussion in this NG - possibly
your address and telephone number, then contribute it,
or else be for ever dismissed as a cowardly child.

You really must get out of this habit of yours of
chanting infantile untruths; it does you no favours.
I did not accuse anybody of being a pirate as you
imply below.

As to using one's own name, I used to until my
family was subject to malicious and threatening
correspondence coming from Stephen G Bryan G0SGB.
I advise anybody to remain anonymous as there are
malicious and obsessive loonies to be found in this NG
and in this thread to this day.

You also seem to not understand the tradition
of using a pseudonym, in my case for the reason
discussed above - I do not claim to be a font of any sort;
I am merely using a pseudonym.

Once again, you should give serious consideration to
presenting to this NG a persona other than the
insult-sneering infant that you continue to do below.

Grow up, Mike Gathergood!

Stupid boy.

>You should get an 817 yourself - no tuning required!

It's interesting to note that the author makes much of the repair issue in his so-called 'FAQ', where he says:

"Usually such people are a variation of the CB Radio hobbyist; they buy their radios off the shelf and send them back to be repaired"

and also goes on to say, referring to his vision of 'radio hams' (whatever they are):

"They do this with gusto, and also repair and modify their own equipment"

but elsewhere said

"I wouldn't recommend anyone whose background is in transistorised QRP to tackle the neutralising of a compact PA stage with 600 VDC on the anodes after replacing the antenna coupling capacitor "

Is there is a conflict here between the so-called 'FAQ' as laid down, and its practice as suggested by its own adherent? Under what circumstances should others 'repair with gusto' but not consider adjustments to a valve PA? All PAs? Ones with 12V on the anode? What are the limitations here? Is there a safety issue here? Where does one go to get 'a suitable background'? The so-called 'FAQ' should make things clear, not have the issues clouded by postings elsewhere.

But it doesn't stop here. Note that no licence is necessary for the repair of radios, as anyone who wishes can repair them. Neither does the possession of an Amateur Licence bestow a qualification for this activity; it is not specifically mentioned.

But further to the repair issue; the so-called 'FAQ', as noted above, states

"Usually such people are a variation of the CB Radio hobbyist; they buy their radios off the shelf and send them back to be repaired"

but it is apparently a sanctioned activity to have a non-functioning radio, and sell it off in that state, the 'redeeming' factors being that the owner was prepared to repair it, and was intending to repair it; the fact that he did not do so apparently being irrelevant.

So, under this so-called 'FAQ', anyone whose radio ceased to function, but who thought they might have a go at repairing it, and indeed intended to repair it, but in the end didn't for whatever reason ("I can't find a screwdriver to get the lid off") would not have negated their 'qualification' for inclusion in the strange but very limited sect proposed by the so-called 'FAQ'! A mere 'statement of intent', perhaps made years later, will be all that is required to save their bacon!

It would seem that this issue of 'repair' needs to be clarified within the so-called 'FAQ' itself, rather than by passing defensive remarks in other utterances; and to do this as a matter of urgency as there might be safety issues for anyone so encouraged to follow it. Also, it makes the so-called 'FAQ' difficult to follow for its adherents - should there be any - in much the same way that over the years 'operating' has been at various times both held high and then damned.

It would seem that this so-called 'FAQ' is itself in need of serious repair; let us see if the author can tackle that, or whether he merely intends to tackle it but then abandon it in favour of some activity that actually lies within his ambit. It is suggested that for a number of reasons, some possibly legal in scope, he does not republish it until the problems inherent in it are satisfactorily dealt with, otherwise serious issues might arise by any who follow it.

Plus, of course, such a neutralisation isn't that difficult a task- being a
normal process after replacing a valve. I've done a couple of FT101's over
the years and I don't recall the PA being that compact.

Either way, assuming the technician involved had even a modicum of
experience in electronics, it is the sort of job I'd expect them to be able
to tackle.

There's a pretty good book available that covers a lot of the basics:

"Build Your Own Electronics Workshop" by Tom Petruzzellis

ISBN 0-07-144724-5 (McGraw Hill Publisher)

Not the answer to all but gives you some pretty good ideas to use as
departure points as you put your shop together.

But why would he allow "nugatories" (his word) such as truth and
common-sense to spoil his vision of amateur radio? A vision which,
according to this posting from 1999, included an HND-level exam!

Gareth Alun Evans wrote in message

One wonders what would be the point? If 136kHz, 1.8, 3.5, 5, 7, 10, 18,
21 and 24MHz were only available to qualified engineers, what would
they use them for? What could they learn about propagation on these
bands that we don't already know? And, in a world where
mission-critical long-distance comms has already moved to fibre and
satellite, to what use would any new knowledge be put?

Surely it's better to promote the social side of the hobby (and yes Gareth, it IS a hobby) to at least the same extent as the technical side, and the only way to do this is for entry into the hobby to remain "competitive" with other pastimes. The RSGB have shown that they can do this efficiently.

Presumably this is the level of attainment that he himself reached;
had he set it higher, he would have excluded himself!

But it is the so-called 'FAQ' that raises the greatest concern, for he
has now started to bound it with other advice - not written within the
so-called FAQ, but elsewhere. If this was done as part of a
professional's duties, it would be regarded as, well, unprofessional;
but in the context of encouraging newcomers, it is a dangerous and
disgraceful practice.

Should this so-called FAQ should be ignored by all, and a disclaimer
issued by the author? Perhaps an abuse report might be in order if
this not be done in the very near future.

Certainly most professions expect the "established" to encourage and support
newcomers.
Experienced engineers tend to have newcomers as assistants, qualified
teachers have PGCE students to mentor and advise, new police officers are
put with experienced officers, junior Doctors are assign to a registrar,
etc., etc., etc.

Such a system only fails if the "established" person isn't so "established"
as maybe they should be.

This is the kind of deal where you make up your own experience. You sit at a blank bench, and put your project in front of you, and go, "Now, where would I like my power supply, DVM, and scope be sitting while I do this?"

Personally, I like to have everything possible at my fingertips, so I go with a U-shaped bench, a chair on wheels, and two tiers of shelves for stuff.

So use your imagination! Make up the workbench of your dreams, custom-tailored to your very own personal specification. :-)

Have Fun!
Rich

At no time have I indicated that I wasn't prepared to
tackle something of which I had no experience. I was
prepared to tackle it, and was awaiting the appropriate
instructions. How many of those who boast of having
neutralised the PA stage of an FT101 did so without
the manufacturer's instructions thereto, and if they
lacked the instructions, how did they know that their
attempts to so neutralise were successful?

You really do seem desperate to score some
infantile point, Andy GilFillan!

There is this preachertype who comes to campus and he is impossible to ignore because he uses a wireless PA system. Is there a way to get a wireless mic or some other transmitter and piggyback onto his wireless PA system so others can enjoy freedom of speech using his PA? If so, what would we need to do this? Please explain it so a doofus (me) can understand.

I posted the above on related newsgroups and I have learned the following:
1. It's all probably illegal and the Patriot Act will put me in prison forever for even considering it.
2. It's definitely doable but I will need to identify the frequency the wireless mic is transmitting on and find another microphoned transmitter device that will allow me to override his wireless mic with a message of my own.

So the question remains: what is the name of this "microphoned transmitter device" and where can I find one or find the plans for building one?

Thank you.

Firstly, why not identify yourself, rather than hiding like the
infantile coward that you undoubtedly are behind an
anonymising server? (Talking of infantile anonymous
cowards, have you ever thought about joining the
plods yourself?)

Secondly, if anyone is arrested as the result of a malicious
and perjurous complaint, then that arrest, and any corresponding
bringing of Ham Radio into disrepute, is a reflection on the
criminal making the complaint, in this case, Brian Reay, G8OSN/M3OSN,
and not on his unfortunate victim.

Brian Reay subjected me to a vicious, malicious and distressing
campaign of harassment over a number of years when he
repeatedly accused me of sheep-shagging, said that my
wife was a sheep in the bed next to me, and accused
me of drinking methylated spirit. I did not respond to him
other than to chastise him for his grossly offensive behaviour.

When it became apparent that Brian Reay was a schoolteacher,
and had been conducting his sexually deviant campaign when
he was under training at a girls's school in Dartford, Kent,
I responded by suggesting that such a campaign meant that
he was a danger to children. Brian Reay's infantile psyche
could not deal with having the tables turned on him, and
he made a perjurous and malicious complaint to the plods
suggesting that it was I who was harassing him, rather than
the other way about. Brian Reay is a w*nkmason and it seems that
his fellow w*nkmasons in the plods will not take action against him
for wasting plod time in the way that he did.

Bullseye!

Gee, he can use a call sign lookup page, I'm really, really scared!

Maybe I should file a report with the Melksham police.

I'd bet they know who you are, Springy Ol' boy.

What's more childish, a casual insult across the internet or actually
going far enough to get arrested for intimidation across the internet?

I suspect the latter.

If anyone is arrested as the result of a malicious
and perjurous complaint, then that arrest, and any corresponding
bringing of Ham Radio into disrepute, is a reflection on the
criminal making the complaint, in this case, Brian Reay, G8OSN/M3OSN,
and not on his unfortunate victim.

Brian Reay subjected me to a vicious, malicious and distressing
campaign of harassment over a number of years when he
repeatedly accused me of sheep-shagging, said that my
wife was a sheep in the bed next to me, and accused
me of drinking methylated spirit. I did not respond to him
other than to chastise him for his grossly offensive behaviour.

When it became apparent that Brian Reay was a schoolteacher,
and had been conducting his sexually deviant campaign when
he was under training at a girls's school in Dartford, Kent,
I responded by suggesting that such a campaign meant that
he was a danger to children. Brian Reay's infantile psyche
could not deal with having the tables turned on him, and
he made a perjurous and malicious complaint to the plods
suggesting that it was I who was harassing him, rather than
the other way about. Brian Reay is a w*nkmason and it seems that
his fellow w*nkmasons in the plods will not take action against him
for wasting plod time in the way that he did.

If it was your intention to be perceived as a Childish Broadcaster
(CBer), and deliberately setting out to cause offence is most
certainly childish, then continue with your Childish Broadcasting
(CB) such as you use below.

Grow up, Galen Watts!

Stupid child.

Someone had a very good idea about finding dropped parts: vacuum the
floor occasionally* with a sheer filter (women's tights) stretched over
the cleaner nozzle.

Not the most anti-static solution imaginable, but it does work.

* Once every ten years, whether it needs it or not.

Typo (in the third word as well!)

For "their", read "there".

try to find out the frequency:
lend a portable frequencycounter and get close to the speaker.
The frequencyreadout of this counter is the one you have to transmit to
overrule the speaker...
If you are in luck the frequency will be about 433.500MHz..
There are a couple of cheap portophones on this frequency..

Considering your behavior here I sincerely doubt your account of Mr. Reay's actions, especially when you refer to the constabulary as 'the plods,' a strong indication of your own denial of reality. I suspect (there's a word you're used to, eh?) the police reviewed transcripts of your exchanges with Mr. Reay and apparently determined you were the threat, as you were the party taken in to custody.

Source record: 15099

I've pretty much decided on a single 4CX800A. The price seems to be right. I think 200w of carrier might be an appropriate target. I run AM mostly. My next step is to decide on a transformer for the thing. Plan of attack for me is to find a manual on BAMA that uses one tube and see what the transformer specs are. I'll try and do a paper design and come up with the transformer specs that I would need. I hope the two agree. I looked up an alpha design that uses two tubes and found a Peter Dahl transformer for the thing was $425. Ouch!

If you have a particular amplifier in mind that uses just one of these toobs then please say so. I need to get a flavor for the transformers available. I will probably buy another Peter Dahl unit.

I Got my HX-50 up and running last night for the first time. Had to replace the transformer and a recap and so forth. I am poking around to see what I can get out of it powerwise. I got 30w on 75m cw no prob into a dummy load. I guess when all is said and done I will put it on my boss's spectrum analyzer and see what I got to drive a linear with.

I realize that this project could be more expensive than a commercial unit, but I can get many of the parts for free from my boss. He is a real good guy and gives me stuff all the time.

thanks for the help.

regards,
Bob

> I looked up an alpha design that uses two tubes
> and found a Peter Dahl transformer for the thing
> was $425. Ouch!

The Peter Dahl prices are fair but not exactly cheap.

Your best bet is finding a junker linear and "inheriting" the transformer/bandswitching/inductor/capacitor and maybe even the plate choke (although most junkers probably have a burnt up choke and maybe some burnt up bandswitching).

> I've pretty much decided on a single 4CX800A.

I assume you mean an ex-soviet "GU74B"? You can find a lot of designs around the net using that part number.

Tim.

The plods did not check out any transcripts of mine, and took
Brian Reay at his word. I rapidly produced in defence a pile
6 inches thick of Brian Reay's infantile and grossly offensive
remarks to me and the plods had to back down. I had no
"exchanges" with Reay - I merely responded in defence
against him to chasitise him for his gratuitous offensive
onslaughts - not dissimilar from your own.

The trial of the plod Richard Fuller for assault is scheduled
to take place on the 8th February at Chippenham Magistrates'
Court.

My behaviour here has always been in support of the
technical pursuit that is _REAL Ham Radio and trying
to maintain standards of decency in response to the
outbursts of rather silly and infantile people such as
yourself.

Indeed, in respect of your rather silly and infantile behaviour,
if you wish to be perceived as a Childish Broadcaster (CBer)
then just carry on with the Childish Broadcasting (CB) that
you utter below.

No, Gareth.

You are the instigator against Brian. YOU are the guilty man. YOU are the harrassing stalker. Unfortunately, you are too mentally unstable to ever see that.
How your wife puts up with you I shall never know. Maybe she's locked in a trunk in the attic or mummified in a rocking chair?

Frankly I don't care how you perceive me.

You, on the other hand, seem to be perceived by the others on this group as just that you decry, childish.

> My behaviour here has always been in support of the
> technical pursuit that is _REAL Ham Radio and trying
> to maintain standards of decency...

Whose standards? Yours? Do those 'standards' involve assisting newcomers, or do you just call them 'childish' and gloat from your soiled, ivory tower?

Oh for pity's sake.

It seems everyone here knows who you are, where you live etc. So why can't you post under your own name and call sign, instead of some fantastically pompous delusion that you're representative of some font of wisdom?

A font of pomposity, yes. Wisdom and knowledge? I'd laugh if you weren't so incredibly pitiful.

Go build something, follow your own FAQ,
W8LNA

There's no denial of reality in following the example
set by the Oddity Of Ploddity that is the We'll Shite
(All Over You) Constabulary....

At 16:45 on the 3rd July 2000, Bobby Young, an Acting
Inspector screamed at me, "ANY OLD PLOD WILL NOT DO!".
(Perhaps it is no wonder the childish disposition of the
common plod when their leaders behave so badly)

In the evening of 7th March this year, David Hunt W1361
referred to the "common plod".

So.....it seems to me that if it is acceptable for the plods
to use the word, "plod" when discussing the plods with
members of the public, then it is acceptable for members
of the public to use the word, "plod" when discussing the plods,
either with the plods, or with people who are not plods.

W8LNA wrote:
>... especially when you refer to the constabulary as 'the
> plods,' a strong indication of your own denial of reality.

Hi all, Im using the transformer from a Bremi BRL500 linear to make a ham HF linear using four EL519 valves. I need to identify the leads coming from the transformer, I bought the transformer surplus so have no data with it....
Also has anyone got any EL519 valves they will sell....

Thankyou

For as long as you are prepared to illustrate so graphically
the difference between a CBer, an M3/CB Fools' Licensee, a
CBer-Masquerading-As-A-Radio-Ham and a _REAL_ Radio
Ham with his gentlemanly traditions, I am prepared to
watch you bemusedly from the sidelines and to chastise
you for your ridiculous outbursts.

It is important that we as Radio Hams make a stand for
civilised behaviour and decency against the vile CBer,
no matter how he might have slipped into our midst.

Don't you realise how silly and ridiculous you make yourself
look, by indulging in what are essentialy very infantile
abusive tirades in an international forum that is broadcast to
the whole world?

However, if you wish to be perceived as a Childish Broadcaster (CBer)
then just carry on as you are with your Childish Broadcasting (CB).

You, coming as you do from a background as a ship's radio
"officer", really ought to know better. Shame on you.

Grow up, Mike Gathergood!

You keep posting this, like you've dug up some interesting piece of trivia from an obscure source.

Rather puzzling, since I mentioned it myself last week in response to the thread about the "numbers station" conspiracy theory - and it's on my website www.g4kfk.co.uk

The good news is that I phoned SIPgate's head office in Germany to see what I could learn about your malicious caller. The bad news is that until you stop calling me a stupid boy, I'm not going to tell you what they told me.

For as long as you are prepared to illustrate so graphically
the difference between a CBer, an M3/CB Fools' Licensee, a
CBer-Masquerading-As-A-Radio-Ham and a _REAL_ Radio
Ham with his gentlemanly traditions, I am prepared to
watch you bemusedly from the sidelines and to chastise
you for your ridiculous outbursts.

It is important that we as Radio Hams make a stand for
civilised behaviour and decency against the vile CBer,
no matter how he might have slipped into our midst.

Don't you realise how silly and ridiculous you make yourself
look, by indulging in what are essentially very infantile
abusive tirades in an international forum that is broadcast to
the whole world?

However, if you wish to be perceived as a Childish Broadcaster (CBer)
then just carry on as you are with your Childish Broadcasting (CB).

You, coming as you do from a background as a ship's radio
"officer", really ought to know better. Shame on you.

Grow up, Mike Gathergood!

Stupid boy.

Not that obscure to most as it's a web link on your website's home page that you often quote. But then it would be obscure to Pierian Spring who said in this thread:

> I don't follow web links

Or is there was some other really credible explanation, like a lucky guess, divine inspiration, someone else followed the link and told him... or some other dog-ate-my-homework reason?

Cheers & season's greetings.

You will have to experiment, carefully! The mains winding will be the one with the thick leads, of course, so should be easy to identify. You should be able to work out the others by checking the resistances and then measuring the voltages with the supply connected.

Let me guess: You're the inspiration for the Monty Python character 'Upper Class Twit of the Year'? That's amazing, considering you were about 15 years old when they filmed that skit, you were quite accomplished at such a tender age, my accolades!

If you are the example of a _REAL_ Radio Ham the hobby has definately sunk to a low much lower than I had ever suspected possible.

I've got five 'Stupid Childs', is that a separate category or are we in competition? If the latter, I may be behind but I've got the will and desire to win! Fair warning, I'm still in the game! (if I don't laugh myself into a serious injury.)

There's nothing upper class about Gareth.

He's more like another Monty Python character, "The Black Knight" from
The Holy Grail. He just keeps coming back for more and more, never
knowing when to admit defeat.

The filament winding has the thick lead, not the mains winding. HV winding will have a higher resistance. 6 volt and 5 volt windings are very very hard to tell apart with your average ohm meter. The mains winding could be dual voltage 120/240 or.....105/110/115/120 voltages. The use of an amp meter along with real low ac voltage should be used to find which winding is which.

The pursuit of decency and of civilised behaviour should
never admit defeat in the face of an onslaught by a horde
of vulgar and abusive infants.

If we in Radio Hammery retreat in the face of such vulgarity, then
the gates will be left open for the Mongolian Hordes.

For as long as you are prepared to illustrate so graphically
the difference between a CBer, an M3/CB Fools' Licensee, a
CBer-Masquerading-As-A-Radio-Ham and a _REAL_ Radio

I am pleased that you tire of your infantile behaviour. There
is hope for you, yet. But please remember that it is not
just you who is made to look a fool by your behaviour; your
behaviour affects the public face of Radio Hammery, and
thereby affects us all.

Sleep on, awaken refreshed and hopefully of a more mature
perspective than you have presented in your recent posts.

Sorry, I was over on the LinRadio console actually doing ham radio (it's sunrise here) instead of provoking what could be described as the 21st century version of Inspiration for the Sex Pistols.

Where were we? Oh yes,

If you were a real ham radio op you'd be on the radio instead of playing Lord of the Gnats.

Indeed. And here are some seasonal songs specially for you Gareth:

"Santa Claus is Coming to Get Me"

"You Better Watch Out, I'm Gonna Cry, I'm Gonna Pout, Maybe I'll tell You Why"

"Walking in a Winter Wonderland Miles From My House in My Slippers and Robe"

"I Saw Mommy Kissing Santa Claus So I Burned Down the House"

"Have Yourself a Merry Little Christmas While I Sit Here and Hyperventilate"

I don't think he is, I think he's someone who finds himself unhappy with his lot in life and instead of trying to improve what he can (starting with himself) he instead denigrates what's around him in a futile attempt to elevate himself. He draws ridicule like a magnet because he continues to denigrate after receiving helpful and occasionally nasty suggestions to recognize his deluded behavior. A legend in his own mind but a joke that has become all too pitiful and no longer funny after too much repetition in the view of others.

But,
A Happy Holiday Season to all, especially Gareth, I hope you find yourself someday, you've got too much intelligence to waste on that FAQ drivel.

Change what you can, recognize what you can't, and move on.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured

the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One such CB type is the so-called "Not-Ham". Otherwise
known as the CBer-Masquerading-As-A-Radio-Ham, this type
had their background in the hobby that is CB Radio and not
in the technical pursuits that lead up to a coveted Ham licence.
Easily recognised by their boasts of the criminal activity of
11 metre SSB operation, one wonders why they don't go back to
the CB Bands if such bands are dearer in their hearts than are the Ham
Bands? No _REAL Radio Hams associate with those who made an
illegal installation of transmitting equipment before being
in possession of an appropriate licence.

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between a Ham Radio licence and a CB Radio licence. To him, they are sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then tries to classify himself as the equal of the Radio Ham when, in fact, he is nothing of the kind. A sure sign of a CB Radio hobbyist is if he holds, or has ever held, a licence issued under the gangrenous degeneration that is the M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of Radio Hams but who are in reality nothing more than an apology for the failure of a CBer are those class B licensees who falsely proclaimed that they were against the use of a Morse Test to control access to the HF bands, until, that is, a test was introduced at their intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to enable them to handle even the simplest algebraic manipulation for Ohm's Law and thus, the disgraceful Class Ber's in the aforementioned category are not Radio Hams by any stretch of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds, or has ever held, a licence issued under the gangrenous degeneration that is the M3/CB Fools' Licence scheme!

6234. HV transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-23 14:54:26 UTC
From: christine <habla@hotmail.com>
Message-ID: <%dUqf.563$GD6.550@reader1.news.jippii.net>
Source record: 15217

hi!
I just brought home my new HV transformer, which was
made to my specifications.:

primary 230V 22A
secondary
two windings, each:
800-1000-1100-1200-1300-1400V at 2A

in this way I can connect the windings in parallell or
serie for a multipurpose HV power unit from
about 110V - 4000V at 2A depending on what
tubes I'll use in the amplifier.
the transformers weight is about 36kg...(80 pounds)

I am right now building a middlepower using
one GU84 with tunable vacuumcapacitors and rollercoil..
it's easy to add another one for more power and I don't
have to build a new HV power unit :-)

at the moment I use this new transformer in my old, small and heavily
modified GLA-1000 with 4xPL519 (transformer outside the case on the floor,
of course!)
as the original transformer is not giving enough power for those tubes.
not much left of the original GLA-1000, added 160m etc etc

I power the tubes heating with stabilized 40V from a separate transformer
as the tubes, which are made for serial heating, are that much different,
they get voltages from 39-41V in serial and I wanted tto have 40V for
each tube :-)

cheers,

cb

For as long as you are prepared to illustrate so graphically
the difference between a CBer, an M3/CB Fools' Licensee, a
CBer-Masquerading-As-A-Radio-Ham and a _REAL_ Radio
Ham with his gentlemanly traditions, I am prepared to
watch you bemusedly from the sidelines and to chastise
you for your ridiculous outbursts.

It is important that we as Radio Hams make a stand for
civilised behaviour and decency against the vile CBer,
no matter how he might have slipped into our midst.

Don't you realise how silly and ridiculous you make yourself
look, by indulging in what are essentially very infantile
abusive tirades in an international forum that is broadcast to
the whole world?

However, if you wish to be perceived as a Childish Broadcaster (CBer)
then just carry on as you are with your Childish Broadcasting (CB).

You, coming as you do from a background as a ship's radio
"officer", really ought to know better. Shame on you.

Grow up, Mike Gathergood!

Stupid boy.

> >workspace for electronics?

3 more things cross my small mind.

Adjustable mirror, a must have for working on fitted pcbs, so you can see both sides. Also a light shone through the board is handy - but not an anglepoise.

Someone mentioned painted benches: my best one was joined painted steel benches, and I had no problem with the paint finish. It all depends on the type of paint. But I prefer wood to metal, its safer and doesnt short things.

Someone also mentioned the question of social security budget workshops. For these, sheet wood on the bed makes a put-away-able workbench, shelving units can be made from scrap wood, but the one thing I would most recommend for low budgets is a melting pot. With one of these, you can get lots of components off scrap equipment boards, and avoid a lot of part purchasing.

Oh, for visitors: instead of using box numbers, use box names. And make 'em gory :) Brains, best.
Brains, reject
Necks
and other things I wont mention

Interesting; looks very similar to the new Prologix board, which I
support fully. Both use a FTDI virtual RS-232 port chip and Atmel
controller, but the Prologix board has a lower chip count.

It will be good to have a few lower-cost options for USB-GPIB
connectivity out there... the National Instruments adapters are still
commanding silly prices.

Be careful when connecting the windings in series. The increased
voltage may be more than the insulation can handle unless you
specified it that way.

In the Softwire forum there's some VB.NET code for GPIB --
(http://forums.softwire.com) -- written by one of the NATI folks. The
various MCC instruments which support USB can thus talk GPIB. (National
Instruments owns Measurement Computing which owns Softwire.)

6263. Bringing Wood & Douglas into Disrepute

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-23 20:36:40 UTC
From: Pierian Spring <radio.ham@lycos.co.uk>
Message-ID: <1135370200.466793.250570@g47g2000cwa.googlegroups.com>

At one time, Wood & Douglas was a respectable supplier to the
Ham Radio market, although it has long since devoted itself
to commercial markets only.

However, the behaviour of its EXPORT SALES MANAGER, one
Mike Gathergood, who has contributed a great number of grossly
offensive
and abusive publications to this NG in recent days would suggest
that the company has gone downhill very rapidly, and is no
longer a respectable organisation.

It is sad that a once respected company should be reflected
so badly in the appaling behaviour of its senior managers, especially
when his infantile and aggressive comments have been published
into various international news groups.

Indeed, it is surprising that the services someone who exhibits such
silly and infantile outbursts into the public fora that are NG
should be retained after giving the company such a bad press.

Well, you'd better call Alan (G4EEE) straight after the hols and let
him know how I've been misusing the company's phone and email
facilities. I'm sure he'll be very interested to hear from you!

So, Mr Nedlar (obsolete). At some time in your obsolete life you took
some time out to pass an obsolete test so that you could PLAY with some
obsolete code and with no doubt some obsolete radio equipment?

You must be so proud!

Merry whatever floats your boat.

Eric Williams, M3EJO, both in his current incarnation, and in his
previous incarnation of "Micky Taker", illustrates so well why
anybody who holds, or who has ever held, a licence issued under
the gangrenous degeneration that is the M3/CB Fools' Licence
scheme will _NEVER_ make it into the ranks of _REAL_ Radio
Hams with their gentlemanly traditions. Having failed to make
any grade other than that intended for 6-year-olds, he sneers
like a playground loser at his betters who have achieved
qualifications that he so dismally failed to acheive in the 20, or so,
years that he pretended to have an interest.

Eric - once you've made the grade (Yes, we can even arrange a 12WPM
Morse test for you) then you're in a position to comment.

Until then, you're just a poor loser.

Grow up.

WRONG!
I took the test that was required for me to get a licence (only one
class then). What I didn't do was wait until standards had been dumbed
down to a level that allowed idiots like you onto the amateur bands.
As for obselescence...well what are all these Morse signals I hear?
Perhaps we should abolish voice comms eh? After all, that's almost as
old as Morse.

That's very good - I bet nobody else reading this would have thought of putting my name into Google! We can all see now why you're the MD of a Software Consultancy.

So now, having correctly linked me to senior technical sales positions within two well-respected UHF and microwave communications companies, do I still qualify as a "vile CBer" just because I have spoken out against the repeated posting of your warped self-righteous and hypocritical "Frequently Asked Questions"? Or because I objected to your belittlement of the hard work and enthusiasm shown by various members of our scout group?

If so, there can't be much hope for many of us here, can there?

It bothers me because you are a lazy-arsed CBr who thinks he is a
radio amateur. It is your type that has turned amateur radio into
multi-band CB.
Anyway it's time for me to pound the key for a while, so no more
replies tonight.

Grow up, Mike Gathergood!!!

stupid boy.......

Sorry Mike! didn't know you were connected with W&D..

I did buy a 70cms PA kit from W&D 15 years ago, but then got a FT2700,
so never put it together.
I now have a handheld for 70cms, and so dug it out, and put it
together.Worked first time of powering up, but think I may need to beef
up the heatsinking. It is so nice to spend my time increasing my
knowledge of ham radio, instead of kicking others for any shortfalls
they may have!!! (perhaps, to help and educate is the way
forward?????) Ah, well, night, night, and back to 4 meters for me....

I joined W&D well after their activities with amateur radio, though there remain many licensed amateurs, both within the company itself and the network of distributors.

The remnants of the amateur products were divested lock, stock and barrel to G3TUX. Unfortunately Chris closed his business and retired to Guernsey last year, so the only place you'll find W&D amateur products sold now is on eBay.

It's a shame, but the reality is that us radio hams are congenital tightwads!

What you're describing has less than nothing to do with the
Amateur Radio Service, at least as it is defined by Section 97.1 --
'Basis and Purpose' of the FCC regs.

I suggest you examine this link, then find a more appropriate
newsgroup.

Given the representation of Amateur Radio given by one contributor to these NGs, it's a wonder any sensible professional organisation has anything to do with it.

The professional engineer, and many overseas Amateurs, must suspect that the rot set into British Amateur Radio some time late in the G4 series, and could be forgiven for avoiding contact with it as far as possible.

W&D's reputation has probably never stood higher. Professionals understand that; some Amateurs can't even tune up an FT101 properly. How technically inept must they be?

The remarks below indicates everything that is wrong with
the educational and background requirements for the
gangrenous degeneration that is the M3/CB Fools'
Licence scheme and why nobody who holds, or who
has ever held, a licence issued under that scheme will
ever make it into the ranks of _REAL_ Radio Hams.....

Someone who posits that the ability to walk on stilts
is somehow a competitive advantage to Radio Hammery
clearly has _NO_ idea what Radio Hammery is all about!

Not-Ham seems desperate to justify his infantile and gratuious
offensive outbursts. There is no justification for such anti-social,
obsessive, and maladjusted behaviour as he demonstrates.

He is a deranged looney BEYOND ANY SHADOW OF A DOUBT.

He is also very immature if he will not take personal responsibilty
for his own actions.

I have _NEVER_ mentioned my wife's name in this NG, nor that of
my children, nor that of my grandchildren.

Those who seek to do so and cause harassment and distress thereby
are sick in the mind.

As a late G4 callsign, and therefore, it seems, being responsible for the rot that has set into the hobby, I wil inform you a little of my background, Stuart. Having joined the RAF after leaving school, I trained for two years at No:-1 Radio school, RAF Locking, as a Ground Communications engineer. I left RAF Locking, and was posted to RAF Cranwell. Upon leaving the forces, I continued in the domestic electronics trade, (TV, video, computers, etc,) I have 'fiddled' with electronics all my working life, (I am now in my 50's), and have half-filled my house with wonderful bargains, and homebrewed kit, as the love of my life will testify. I have ferric chloride stains on most of the carpets, a well-scorched bench, (soldering iron.....) and, not only can I tune my FT101B, I have also modified it to accept 6146B valves in the output stages, as the cost, and availability of the 6JS6 'bottles' became silly.
I do admit to having held a class B callsign, (G8ZWI) , and cheerfully admit to holding it for a large number of years, because I was too lazy to get off my backside, and do the Morse. My latest constructional project (half finished,) is a home-brew version of the Norcal Sierra, but with an AD9851 DDS & LCD in place of the normal VFO tuning. I will try to contact you, if I have any problems, although I am not too sure you will be willing to help a lowly, late, G4,

(P.S. I believe Santa Claus is bringing me a Yaesu FT817, with c.w. filter for Christmas. Should I send it back???)

For as long as you are prepared to illustrate so graphically
the difference between a CBer, an M3/CB Fools' Licensee, a
CBer-Masquerading-As-A-Radio-Ham and a _REAL_ Radio
Ham with his gentlemanly traditions, I am prepared to
watch you bemusedly from the sidelines and to chastise
you for your ridiculous outbursts.

It is important that we as Radio Hams make a stand for
civilised behaviour and decency against the vile CBer,
no matter how he might have slipped into our midst.

Don't you realise how silly and ridiculous you make yourself
look, by indulging in what are essentially very infantile
abusive tirades in an international forum that is broadcast to
the whole world?

However, if you wish to be perceived as a Childish Broadcaster (CBer)
then just carry on as you are with your Childish Broadcasting (CB).

You, coming as you do from a background as a ship's radio
"officer", really ought to know better.
Indeed, it is difficult to see, in the light of your
well-demonstrated infantile disposition, how you could
ever have been the export sales manager for a well-
respected company such as Wood & Douglas.

Shame on you. You should know better. What on Earth would Alan
Wood G4EEE think of the bad publicity you are visiting on
his company?

Grow up, Mike Gathergood!

Stupid boy.

Some confusion on your part, I think, because the post to which
you are replying was addressed to Stuart Crowe in response to
his rather silly and infantile gratuitous remarks directed at me.

You, however, seem to be F.Cooper, and the post to which you
reply was not addressed to you.

With a quick GoogleMiner session, neither your email addresses
nor your NNTP programs are the same.

Like a number of new contributors to this NG, you very rapidly
metamorphose into an aggressive challenger, for what reason
I do not know.

The answer to your question is that, yes, I never originate
personal attacks, I only ever assert the right of reply, and
the right of chastisement when answering posts that are
somewhat infantile as I did in the post to which you responded.

It is important that any self-respecting _REAL Radio Ham makes
a stand for decency and for civilised behaviour, a course of
action that I admonish you, in your turn, to follow.

You don't listen to many amateur then Walt. A definite trait of the radio amateur is "short arms and deep pockets"- a positive trait in my view but still worthy of a bit of mirth. I like a bargain as much as the next man and (re)using a bit of "junk" to repair or make something is far more pleasing than flashing the credit card.

I don't see why you'd draw that conclusion, Fred, since my post clearly referred to one particular contributor. Rot generally takes time to spread, and starts out with a small area of contamination. There are still some good people coming into the hobby even now judging from the bands.

> (P.S. I believe Santa Claus is bringing me a Yaesu FT817, with c.w.

You kiddies are not real Hams. In order to be a REAL Ham you have to do what
I did...be retested.
And not just everybody can be retested...you have to have a special
'invitation' from Riley Hollingsworth himself.
I know. I've tested twice.

You are a LIAR.

I have _NEVER belittled any "of the hard work and enthusiasm
shown by various members of" your "scout group"

I did not even know that you had a scout troop.

But since you raise the issue, if they are, indeed, scouts
and are over the age of 11 years, and they have had to put
in "hard work" to pass an exam intended for 6-year-olds,
then they are not achievers but retards.

If you do not wish for there to be a right of reply, then you
would be better served if you do not contribute at all.

I did not say that you do not live up to my "ideal radio amateur";
in fact, I do not even use the term.

To the contrary, from what you have posted recently, you do
seem to be a _REAL_ Radio Ham in (most of) the best
traditions thereto.

A Merry (Belated) Solstice to you, also.

Definition of a sociopath, for those who were wondering:
Diagnostic criteria (DSM-IV-TR)
The Diagnostic and Statistical Manual of Mental Disorders, a widely used manual for diagnosing mental and behavioral disorders (see also: DSM cautionary statement), defines antisocial personality disorder as a pervasive pattern of disregard for and violation of the rights of others occurring since age 15 years, as indicated by three (or more) of the following:
- failure to conform to social norms with respect to lawful behaviors as indicated by repeatedly performing acts that are grounds for arrest
- deceitfulness, as indicated by repeated lying, use of aliases, or conning others for personal profit or pleasure
- impulsivity or failure to plan ahead
- irritability and aggressiveness, as indicated by repeated physical fights or assaults
reckless disregard for safety of self or others
- consistent irresponsibility, as indicated by repeated failure to sustain steady work or honor financial obligations
- lack of remorse, as indicated by being indifferent to or rationalizing having hurt, mistreated, or stolen from another

WoW some transformer! That one will do a full gallon and then some
without breaking a sweat! I hate to ask what it cost! Sounds
like a universal replacement for any tube linear.

There's no reason to ask myself the same question.

My position here is that I'm making a stand for
decency and civilised behaviour against the
gratuitous and offensive onslaught of a few
CBers who really ought to know better.

If more stood up for decency, things would improve.
Who was it who quotes, "'For evil to triumph it is only
necessary for good men to do nothing'"?

Oohh! - it is someone by the name of , "Mike Clayton" -
anybody that you know?

I find it strange that you seem to have no dispute with
those who originate the most offensive of personal
insults and yet you criticise those who defend themselves
and stand up for decency.

I suggest you use the BAMA site, but if you have a problem, email me if you
want me to email them to you. The schematic is in three sections.

There aren't any likely fault possibilities in the receiver that would cause
a voltage on the antenna terminal. What type of voltage do you see, how
much, and if it's DC what is the polarity?

Even if the capacitor (C33) on the grid of the RF Amp was shorted, you would
measure nothing, because the slight voltage would be well grounded through
the inductors.

There is no mention of any scout troop in what you quote.

Indeed, that you associate your scout troop with the
phrases, "gangrenous degeneration" and "M3/CB Fools'
Licence" is very revealing - no one but you has made
that association.

Every part of the FAQ, where it criticises the M3/CB Fools'
Licensees is as the direct result of encountering them
and their ridiculous behaviour in this NG. Indeed, if you
are responsible for training such licensees, perhaps it
is from you that their anti-social tendencies arise?

Once again, you resort to rather silly and infantile forms
of abuse, "pathetic sociopath" and "bitter and twisted".

Shame on you, Mike Gathergood, you ought to
know better at your age, and your pubic face, which
is also the public face of Wood & Douglas, does
them no favours.

Grow up.

Stupid child.

For as long as you are prepared to illustrate so graphically
the difference between a CBer, an M3/CB Fools' Licensee, a
CBer-Masquerading-As-A-Radio-Ham and a _REAL_ Radio
Ham with his gentlemanly traditions, I am prepared to
watch you bemusedly from the sidelines and to chastise
you for your ridiculous outbursts.

It is important that we as Radio Hams make a stand for
civilised behaviour and decency against the vile CBer,
no matter how he might have slipped into our midst.

Don't you realise how silly and ridiculous you make yourself
look, by indulging in what are essentially very infantile
abusive tirades in an international forum that is broadcast to
the whole world?

However, if you wish to be perceived as a Childish Broadcaster (CBer)
then just carry on as you are with your Childish Broadcasting (CB).

You, coming as you do from a background as a ship's radio
"officer", really ought to know better.
Indeed, it is difficult to see, in the light of your
well-demonstrated infantile disposition, how you could
ever have been the export sales manager for a well-
respected company such as Wood & Douglas.

Shame on you. You should know better. What on Earth would Alan
Wood G4EEE think of the bad publicity you are visiting on
his company?

Grow up, Mike Gathergood!

Stupid boy.

If it is 16-pin, I'd be inclined to suggest it has the standard pinout that is
common among HD44780 type 16*2 displays. This would be especially so in the
event that there is pin numbering on the board, and the sequence is
16-15-1-...-14. Pins 1-14 would be the standard config, 15 & 16 for backlight.

Just my experience with many types, although Seiko-Epson haven't always aligned
with the rest of the world on pinouts.

The only "hobby" around is CB Radio.

Ham Radio is a technical pursuit.

Newcomers to Ham Radio are those who
are naturally interested in technicalia and
who drive themselves forward. Such people
will have no interest in a licence issued
under the gangrenous degeneration that is
the M3/CB Fools' Licence scheme.

To have introduced such a scheme whose
sole purpose is to maintain the profit
levels of a CB (Sorry, "seedy"!) book
publisher was evil indeed.

Hey if you are interested I have the EXACT same unit that the above link
points to (except mine was OEM'ed by Lafayette radio and has their name
on it). Is it worth anything near what the audiovox unit sold for?

>
> 73 de Sven LA6KJ

If it is based on the Hitachi HD44780 chip, it is probably
pin compatible with similar displays from Hitachi, Seiko,
Densitron and others. I have seen a few LCD modules that
don't use the HD44780 but are still 100% compatible with
it. Check the numbers on the IC's. Send us a link to a
photograph of the module. If all else fails, try using
the pinout for the Hitachi displays and hope for the best!
Displays without backlighting usually have 14 pins. Displays
with LED backlighting usually have 16 pins.

From a Seiko 2x20 display data-sheet:
1 VSS GND
2 VDD Power supply voltage +5 V
3 VLC Liquid crystal driving voltage
4 RS H: Data register; L: Instruction register
5 R/W H: Read; L: Write
6 E Enable
7 DB0 Data Bus Line
8 DB1 Data Bus Line
9 DB2 Data Bus Line
10 DB3 Data Bus Line
11 DB4 Data Bus Line
12 DB5 Data Bus Line
13 DB6 Data Bus Line
14 DB7 Data Bus Line
15 A Anode
16 K Cathode

Don't let the smoke out of it.

Harry E. Landsberg, Jr., CIA Maltese Falcon: Kennedy assassination,
IRAN/CONTRA, UFO's

My late father, Harry E. Landsberg, Jr. is apparently one of the 35 CIA
Officers memorialized on the north wall of the Original Headquarters
Building lobby whose "names ... must remain secret, even in death."

Please see:

http://www.angelfire.com/journal2/landsbergphotos2/maltese_falcon_search_terms_maltese_falcon_cia_dot_gov.jpg

taking note of the search terms "maltese+falcon."

Then:

http://www.angelfire.com/journal2/landsbergphotos2/maltese_falcon_cia_dot_gov_memorial_wall.jpg

and

http://www.angelfire.com/journal2/landsbergphotos2/maltese_falcon_cia_dot_gov_memorial_wall_2.jpg

---

I was discredited as being mentally ill in 1981 and again in 1985. As
a result I was motivated to research family matters.

In 2004 I learned that my husband, Richard Hanning, Jr., was a
Marine/covert operator assigned to me. We met in 1985 and I knew I was
a target when I met him. I just didn't know I was his target.

We are divorced. My life has been in danger and I have been revealing
information about my family and their associates as a result.

Please see:

"Harry E. Landsberg, Jr. -- resemblance to man in photo with Specter"
http://home.earthlink.net/~lhann10243/index.html

and

"IRAN/CONTRA: Fleming O. Landsberg, Fleming Landsberg, U.S. Ordinance
[sic] Inc."
http://home.earthlink.net/~lhann10243/id85.html

and

"Landsbergs and Maddens -- Mirror" (UFO's)
http://www.angelfire.com/journal2/landsbergphotos/Landsbergs_and_Maddens_mirror.html

---

I am a survivor of satanic ritual abuse and mind control.

Please see:

"The Love Game"
http://home.earthlink.net/~sammark4/id2.html

and

"Scars and other signs of mind control"
http://home.earthlink.net/~sammark4/id5.html

My legal mother, Donna Jean Volkmer Landsberg, worked as secretary to
the Undersecretary of the Navy in the 1940's, likely James Forrestal.

He died under mysterious circumstances. Please see:

"The Death of James Forrestal" by Richard M. Dolan
http://keyholepublishing.com/Death%20of%20James%20Forrestal.htm

---

I had a vision of Donna as a three-headed bird (black heads.)

I was searching for photos of Vanessa Redgrave and found this photo
which was similar to the bird in my vision:

http://www.angelfire.com/journal2/landsbergphotos2/donnas_bird_head_more_like_this.jpg

Then searching on "Maltese Falcon" I came across "The Virtual Tour of
the CIA:"

http://images.google.com/imgres?imgurl=http://www.cia.gov/cia/information/
tour/83stars_lg.jpg&imgrefurl=http://www.cia.gov/cia/information/tour/
stars.html&h=465&w=600&sz=184&tbnid=fQ8WESE-YHkpWM:&tbnh=103&tbnw
=133&hl=en&start=130&prev=/images%3Fq%3D%2522maltese%2Bfalcon
%2522%26start%3D120%26svnum%3D10%26hl%3Den%26lr%3D%26sa%3DN

or

http://www.cia.gov/cia/information/tour/stars.html

There is no mention of the words "Maltese Falcon" on the page.

There was a Divine Intervention in late 2003 and I have been protected
as I have been enduring harassment in the astral plane.

6359. No link attitude!

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-26 04:30:26 UTC
From: n9zle <NoSpam@nospam.com>
Message-ID: <ClKrf.37463$dO2.281@newssvr29.news.prodigy.net>
Source record: 15092

No link attitude!

http://www.n9zle.com/forum/

What is it with this no-link to other site attitude?
Years ago when the internet was in its infancy just about any site would add your site as a link from theirs. In return you would do the same. But now it has come to NO-LINKS. Not even in the forums. I have had a website located on tripod for about 9 years over those nine years I had a link to qrz dot com That site received over a million hits. And many users went from that site to qrz and on-to Icomamerica dot com. I have always supported Icom. They have never given a link on their site to mine. I have always supported qrz. But of course he(AA7BQ) never put a link on his site to mine. Well you may say that "I never asked". And that is true. But recently I have noticed he has been deleting my posts. ALL OF THEM. He never contacted me telling me why. AA7BQ just deleted them. I build CIV cables and sell a few of them every week to amateur operators who want them. When I posted one on his site. I found he deleted the post soon after it was placed there.

My beliefs are.
1. QRZ AKA AA7BQ no longer has the amateur radio attitude.
2. AA7BQ has gone fully commercial but calls his site "The Ham Radio Super Site"
3. AA7BQ does not have your best interest in mind.

I can also prove what I am writing here.
For one if he claims he is nothing but a commercial site then why does he ask for donations?
If he is not a commercial site than why will he not allow me to post my CIV cables on his site?

That takes care of number 2
Now for number 1 and 3. If some one knows the truth about something but keeps it from you he is a liar.
No mater how you put it, he is a liar. On the QRZ site Fred is there to help you renew your license. Or so he leads you to believe so. He charges you for it. Mr. Lloyd has never revealed it to any amateurs that you can renew your license or do an address change at the fcc.gov web site for FREE. Yes TOTAL FREE at the FCC web site.
The forms at the FCC web site or no harder to fill out than his.

His CD. He charges 24.95 plus tax and shipping. On that CD is data he obtained from the FCC and got it for FREE, he sales it to you. Also he has software, created by programmers like MYSELF. And MODS that have been made available from the manufactures and other HAMS like ME! I have been contributing to Amateur Radio community for greater than 10 years, and have

received very little for software I created. Never complained when it was copied. I have performed and created several of the MODS for various transceivers. Never asked a penny for it. I never commercialized HAM RADIO. And NEVER took money from some one for something they could get FREE else where.

I am sure many of you would like to ask me "what I am going to do about it?" Here is my answer.

I have created an open forum on my web site http://www.n9zle.com/forum/

There you can post a link to your own site even if it is a commercial site. You can post any ham radio equipment you have for sell on the site.

You can do a callsign lookup at my site from the FCC database, not that stupid qrz thing.
I will soon put together an open source database that I will sell for the price of the CD plus the true cost of shipping. About two bucks total. Once you install the database on your system, you will be able to download updates for FREE. I will make drivers available to programmers to access the database in several different languages and operating systems. I will also attempt to make the database available on the internet for FREE to download.

I only ask for a little help from other HAMS like myself. I need a few elmers that are willing to moderate some of the forums. It is easy and you will find it fun. If you have any suggestions on new forums or sections please logon to my site and make a post.

lol!

actually it wasn't very expensive. it's custom made by
a transformer manufacturer and the price was some
340.-E which will add up to a little more in US-dollars

i thought first on making it with a ferrite core to save some
space and weight, but they said there is an insulation problem
with high voltages and the cost would be much higher...

cheers,

cb

I need to generate 6v DC and 90v DC from a 12v DC automotive electrical system to power an RT-70A/GRC surplus military radio. I need about 250 mA at +6 volts and about 75 mA at +90 volts. I was thinking about using the guts from an old battery back up but it would be a bit of a kluge. Are there any 90 volt regulators in the 78xx series? How do I get the voltage up to where I can get something that I can get the 90 volts from. Getting the 6 volts doesn't seem to be a problem. A 7806 off the battery should work for that unless any of you can see a problem doing that. Maybe the common common would be a problem. Right now I'm running it off of an HP6299A and an HP6236B with commons jumpered. I'd like to be able to go portable with it.

6366. Antenna gain vs. isotrophic (teorethical) one

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-27 02:09:34 UTC
From: Spajky <Spajky@##volja.net>
Message-ID: <td81r1lhbi1f0b5p9bba6pfcr64iqnbjja@4ax.com>
Source record: 14999

Hi guys,
hope that someone will clarify me certain doubts!

The problem: I have 2 different sources (some book, something DL-ed
from net) stating that approx.:

-isotrophic antenna (teorethical all around ball space HF radiation of
a single round point) has only 2,15dB less gain than half wave di-pole
(=2nd source)

- the book instead says that 1/4 lambda antenna has -3dB worse gain
that same dipole as before, [5/8 one just -1dB] & so my thought is,
that 1/4 antenna must be better than isotrophic one, since even if it
radiates 360° horizontally (if vertical polarized-mounted); vertically
it does not more than 120° both sides (all around).

I believe that on second source there is a mistake & was ment
that isotropic is 2 dB worse than 1/4 antenna & not 1/2 dipole.

so, it would be so IMHO : 0dB isotropic one
+2dBi 1/4 one
+5dBi 1/2 dipole (3dB more than 1/4 one)
Am I write or wrong?

You can build a step-up or flyback with the LM3478. Tough to solder
though, it's a TSSOP package. Don't know what current you need but just
pick a suitable FET.

For 6V I'd use a buck regulator instead of wasting 50% of the energy in
a series regulator.

Regards, Joerg

I'd use one of those small inexpensive inverters which put out 120vac
and then use a conventional transformer/rectifier system. You can pick
up the inverter at any truck stop.

6370. Re: Antenna gain vs. isotrophic (teorethical) one

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-27 04:15:41 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <11r1fveeaps4ib8@corp.supernews.com>
Source record: 15002

dB is a ratio of two gains or other quantities, so gain expressed in dB is meaningless unless both antennas being compared are specified. dBi is a common way of expressing the gain of an antenna, and its meaning is universally accepted and unambiguous -- it's the gain in dB relative to that of an isotropic antenna.

Let's begin by assuming that all antennas are perfectly efficient. That is, all power applied to them is radiated and none turned to heat. This assumption is a valid one for most antennas of a reasonable size in terms of wavelength. For other antennas, the assumption is useful because it separates loss, which can be modified by construction, materials, and other factors, from more fundamental phenomena which can't.

Given that assumption, the first important point is that no antenna can have a gain lower than 0 dBi (the gain of an isotropic antenna) in its most favored direction. If it did have a gain lower than 0 dBi in some direction, it would have to have a gain higher than 0 dBi in some other, because the only way gain can be increased in a perfectly efficient antenna is by robbing radiation in one direction in order to increase it in another.

The next important point is that a thin half wave dipole in free space has a gain of about 2.15 dBi. If you make the dipole shorter, the gain decreases slightly due to a change in the current distribution. When the dipole gets vanishingly short, the gain has dropped to 1.76 dBi. In practice, the loss increases dramatically when a dipole is made very short in terms of wavelength, so this gain can't be achieved in real life. However, the loss depends on construction, materials, and other factors which can be controlled to minimize loss when needed. The gain of a lossless quarter wave dipole in free space is about 1.84 dBi. The loss of a real quarter wave dipole can usually be made negligible, although attention also has to be paid to matching network components to keep the system loss low.

Over a perfect ground plane of infinite extent, the gains of antennas typically increase by about 3 dB compared to free space. In the case of a free space dipole vs. a quarter wavelength antenna over a perfect ground plane, the difference is exactly 3 dB. This is because they have exactly the same radiation pattern (except of course, that the half pattern of the vertical below the ground plane is missing), but the same amount of power is being concentrated in half the volume. Consequently, the gain of a 1/4 wave vertical over a perfect and infinite ground plane is about 5.15 dBi. This also can't be achieved in practice because there isn't any such thing as a perfect ground plane of infinite extent. You can come close if working over salt water, but nowhere near if the

ground plane is dirt.

==========

Those 'inexpensive inverters' might need some attention in respect of
the 'hash' they create , possibly causing interference in the receiver.

Frank

90V @70ma is only 6.3W and a step-up of no more than 90/12=7.5. This
would be something like a 24VAC center-tapped transformer turned
backwards with a multivibrator drive of the secondary at 50-60Hz and the
usual primary is rectified and capacitor filtered to produce the 90V.
Since the reflected current is only about 1/2A, you can then feedback
the rectified HV to drive an error amp that regulates the center tap
down to 9V or so.

Hello James,
Speaking as a cheapskate ham/hobbyist, how
about salvaging parts from a computer power supply.
Find a dud power supply for free at computer
shops/dumpsters/rubbish tips/roadside etc.
Salvage the TL494 integrated circuit that can
be found in many computer power supplies.

You could build a 90 Volt power supply as
Ray Robinson has down here
http://www.shlrc.mq.edu.au/~robinson/Information/Inverter_4W.html

Here is a link to the TL494 Data sheet
http://focus.ti.com/lit/ds/symlink/tl494.pdf

This link tells you how to use the TL494 IC
http://focus.ti.com/lit/an/slva001d/slva001d.pdf

Use another TL494 in a buck converter for your
12 Volts to 6Volts power supply module.
Look at the bottom of this page for more info.
http://focus.ti.com/docs/prod/folders/print/tl494.html
Your 7806 is probably a better idea, saves a lot
of messing about.
Or
you could use the guts of a mobile phone
car charger. The charger that fits into the
cigarette lighter in a motor car.

You can find them in pawn shops for a dollar
or two. Dud ones even cheaper. Usually
just a broken connection from rough handling.
http://www.onsemi.com/pub/Collateral/MC34063A-D.PDF
Look at page 7 Figure 10 Step down converter.

In the few car phone chargers that I opened,
the IC was a MC34063 and the schematic was
very similar to that shown in figure 10
Just change R1 or R2 slightly so that you
get 6 Volts out.
You may have to check/change the value of
resistor Rsc to be closer to that shown in figure 10
You might even get away with not changing the
inductor. Try it and see if the original inductor
works well enough for you.

A ton of reading, bits and pieces for free
or dirt cheap.
What a great hobby, this is James, eh!

Regards,
John Crighton
Sydney

6374. OT need HX-50 schematic please.

Newsgroup: rec.radio.amateur.homebrew

Source record: 15007

I am restoring a Hammarlund HX-50 for a fellow ham. The BAMA schematic is...quite bad. I am having trouble tracing and verifying the components of the unit. The rest of the manual is rather good in DjVu format. The owner has a reproduction manual on order and we hope it has a better schematic.

In the mean time I would like to get started and order caps, resistors, etc. Could a kind soul please email me a copy of the schematic? Also my parts list resistor section starts with R165. There seems to be a missing BAMA page in between pages 43 and 44.

Also, is there a better forum for such a request?

Thanks to all,
Paul
www.ppinyot.com

BTW - if you would like a stand alone (not plug in) DjVu application go to: http://www.tuberadio.it/utils.htm It is slick. I have combined many jpgs and gifs into a single file. The resolution is surprisingly good for the overall compressed file size.

Hello again James,
I just came across this site while looking
for something else.

http://web.telia.com/~u85920178/use/tubepsu.htm
Look at the the 6V AC from 12 V DC. Nifty!

Here is another
http://www.i4at.org/lib2/inverter.htm
You want DC out so you will have to fit a bridge rectifier
and filter capacitors to the output of the transformer
just like Harry Lythall's circuit above.

Regards,
John Crighton
Sydney

Roy, thanks for detailed explanation :-) I got now some stuff
clarified even more than enough! :-)

(btw, the old book I mentioned was written 20y ago from a "local"
radioamateur [prof.& dr.] one, I use it much. & there I saw the
comparision chart of different type of basic antennas; so must be
kind of a mistake there like it looks, the reference of 0dB was set as
halfwave dipole there...)

Roy I have also another 2 quick questions for short answers:

- if I connect to a 50ohm TX out a cable of 75ohms (w/o "perfect"
Z transform add_on there), I can aspect approx. 1: 1,5 SWR [50:75]
& because of Z miss-match I will loose no more than 0,5dB (that same
my book states for that SWR in some diagram); yes I know that is in
"ideal" conditions & TX is only 50mW ... could you confirm me
briefly that?

- next : twin-lead/symetric cable of only half wavelenght (or 3x,5x
etc. half wavelenghts, shorted by a velocity factor sure) mirrors the
input Z to its end; does a coaksial cable do the same at the same
lenght or for that is a different simplified formula?

TIA!

No, you would lose 0.18 dB if your source is something like a signal generator with fixed 50 ohm output impedance. If you match the impedance so the source sees 50 ohms, you'll regain the 0.18 dB.

>
> - next : twin-lead/symetric cable of only half wavelenght (or 3x,5x

All transmission lines transform impedances the same, regardless of construction. However, the impedance seen at the input of an integral number of half wavelengths of real transmission line won't equal the load impedance, because of line loss. The error will be small if the load impedance is about the same as the line Z0. But if they're quite different, even a small amount of loss will change the input impedance a significant amount.

....to put things straight:
isotropic antenna has 0dB gain by definition and is called 0dBi (dB
over isotropic)
quarter wave vertical over ground plane has 0.13 dBi gain.
a dipole IN FREE SPACE!!!! has a gain of 2.15 dBi.
a 5 eights wavelength vertical has a gain of 3 dBi.
this is holy writ!
so now you have them set up in correct order.
just add the lower gain from the higher one to get the difference.

Google "GLOWBUGS" as there are a number of small tube based sites
that have dealt with this problem.

Do it the way the original radio did it -- dynamotor. You can still find
them in the back room at a lot of military surplus electronics junk stores.

But then be prepared for some major restoration. The bearings of a lot
of these are nearly shot, mostly from sitting in an attic for decades.
It's like old pond pumps. They run fine for a few weeks and then the
racket increases, some weird noises appear, things get hot and they
seize up.

I restored an old Hammond organ. These generate the tones in a similar
manner. A motor (plus a start motor) and over a hundred pickup coils on
the long secondary shaft. 20 hours of hard work got it going again but
we have accepted the fact that some of the bearings are pretty much over
the hill. So it needs 2-3 starts to coax it to run without that mild
screeching in the background. Getting spare parts from a company that
went out of business 30 years ago just isn't going to happen.

So, put the cam thingie on some sort of spindle, with some kind of
depth gauge thingie, (maybe a slide pot and a stick), and map the
disks, and just make the same waveform from ROM?

Good Luck!
Rich

The folllowing is from the URL: http://www.fuckchristmas.org/

This is a F-N MASTERPIECE. ENJOY you mother-fucking assholes. (grin)

Oh man, fuck Christmas.

Seriously – are you kidding me with this “There’s a war on Christmas” bullshit? FOX News wasn’t raking in enough cash already from all the Christmas commercials for Kill ‘em All Barbie and Girls Gone Wild Brand Toddler Gear? They had to start publishing books about some bogus attack on Christianity? And who did they pick to lead this particular charge?

John fucking Gibson. This guy has wiener written all over him.

Bill O’Reilly gets all the credit as the biggest nutcase in FOXville, but Gibson really deserves his own special wing in the happy house. This motherfucker’s embedded assignment reads “Up Karl Rove’s ass.”

What makes him such a dick? I mean, besides making a fortune by screaming hysterically about how oppressed Christians are by the other twenty percent? How about advocating bombing countries that don’t vote the way we want in their own elections? Way to encourage democracy, fuckhead. And maybe he was kidding when he wished, on air, that the French had gotten the 2012 Olympics instead of the Brits so the terrorists would “blow up Paris,” but it might have been just a touch over the top to call for it again on the day of the London train bombings. Classy move, asshole.

And really? That’s just scratching the fucking surface. Anyone remember who was responsible for the bombing of the Federal building in Oklahoma City? John does: Iraq. And speaking of Iraq, Gibson thinks Rove deserves a fucking medal for outing that CIA agent. And, like any good reporter, he wanted to burn the Florida ballots after his buddy Bush got “elected” rather than, I don’t know, count them? “Is this a case where knowing the facts actually would be worse than not knowing?” That right there is why sometimes it’s useful for journalists to go to, what do you call that fucking place? Oh yeah, journalism school.

And now he's all worked up about Christmas being stolen. What is this, the fucking Fairytale Network? It's a national fucking holiday and we're spending gobs of our hard-earned tax dollars on wreaths and lights for your special Santa day. But these bastards are all "But they call them Holiday trees!" Here's a clue: no, they fucking don't. Ok, maybe in a couple places, like on FOXNews.com and at the White House, but if Christmas is under attack, I'm Kris fucking Kringle.

And guess who's stealing Christmas, according to Gibson. Go on — guess. "A cabal of secularists, so-called humanists trial lawyers, cultural relativists, and liberal, guilt-wracked Christians — not just Jewish people." (Emphasis mine. Pure, unadulterated anti-semitism, his.) A cabal? Are you fucking kidding me? Could we try to be a little more fucking original with our Jew-hating?

Speaking of Jew-hating, Pat Buchanan has joined the hype-a-thon of the supposed Attack on Christmas, too. Or, as he put it, "What we're witnessing here are hate crimes against Christianity." Sorry? We're not so hot on paying for an inflatable camel for your goddamn nativity scene and suddenly we're Slobodan fucking Milosevic? Fuck you. Get some goddamn perspective, you little prick. When they start hunting Christians in the streets, it'll be time to start yelling "Hate crime." And no, it won't count when they start chasing you with the torches. That'll be called "The Most Wonderful Time of the Year."

And Bill O'Reilly, Gibson's cellmate in the silly shack, is doing his part to save Christmas, too. He's been going after New York's Mayor Bloomberg (that Commie) because he says the Christmas Tree at Rockefeller Center has been renamed a "Holiday Tree," and "No Christian Christmas symbols are allowed in the public schools." The only problem? Neither of those things is even remotely fucking true.

It takes some super-sized balls for O'Reilly to get all lathered up about sinners and their fictional anti-Christian crusade. Every fucking person on the planet has hard and fast evidence that Bill is a world-class pervert, but still he feels totally justified lecturing the rest of us on our moral inferiority.

How fucked up is Bill O'Reilly? Pretty fucked up. Everyone got so crazyfaced about him confusing a sponge and a Middle Eastern snackcake (pretty fucking funny, mind you), that they missed the scary bit: what he meant to say. Old Bill wanted to get all funky on his intern like this: (you'll excuse my foul language, I'm quoting an award-winning newscaster here) "I'd take the other hand with the [loofah] thing and

put it on your pussy."

loofah (lū'fə) noun. A natural exfoliating sponge.

exfoliate (ĕks-fō'lē-āt') verb. To remove
(a layer of bark or skin, for example) in flakes
or scales; peel.

That's right. Bill O'Reilly, fount of morals, is super
familiar with the female anatomy. So much so, that
he knows how good it feels to have one's pussy
exfoliated. We're talking h – o – t, Hot.
That's exactly who I'm going to for my life lessons.

Sorry, where were we? Oh yeah, fuck Christmas.

Can we back up just a couple steps here? At what
point did a basic understanding of the separation
of church and state become a fucking war on religion?
And how did we get to the point where you can call
an organization set up to defend our civil liberties
"Terrorists" on national television and no one fires
your ass? Enough. Fuck all of you lying little shitheads
who wish the world was out to get you so you could
play the poor oppressed victims. Wake up assholes
— you're the cowboys, not the fucking Indians.

"But we want to display our Christmas tree on city property!"
You can, go right ahead. "They're stopping us from
praying in school!" They're not, so fuck off. "We're
not allowed to say 'Merry Christmas' anymore!" Are you
fucking kidding me? Knock yourself out. Say it at work,
scream it in your high school lunch room, hell, tattoo it
on your fucking g-ddammed slooped forehead for all we care.
Guess who's gonna be there defending your right to do
every one of those things? The fucking ACLU. One of
these days you bastards are going to drive those fuckers
out of business, and then you'll see some actual attacks
on your religious liberties. I thought conservatives
were supposed to be all proud and independent?
When did they turn into a bunch of fucking crybabies?

Let's back up even fucking further, shall we?
Can anyone tell me how old Christmas is? Anyone?
Two thousand years, give or take, right? Gee, who's
been reading their No Child Left Behind History Textbooks?
Try fucking four thousand years. Huh. Twice as fucking
long as your little baby king has been around. How
could that possibly be, unless. . . waitaminute. . .

Christmas isn't fucking Christian. Ok, now we're talking.

That’s right, that Yuletide cheer you’re spreading? What exactly do you think Yule is? It's the fucking Pagan celebration of solstice. And those “Christmas” traditions? They’re not just *like* Pagan rituals, they fucking *are* Pagan rituals. Way before your Jesus got all magical with the bread and fishes, the Romans were celebrating the birth of Mithra on . . . guess? Go on – guess. December fucking twenty fifth. What a weird coincidence, eh shithead..? Practically the whole thing is ripped off from the fucking Druids and the Romans. Twelve days? Check. Exchanging gifts? Check. Mistletoe? Check. And you’d better fucking believe that those decorated trees that Gibson and Co. are so bent out of shape over are as Pagan as the Rune and Crystal Shack at Pentagramfest 2005. You might as well be building miniature fucking Stonehenges in your den or rec room alongside the bar.

And don’t you read your own goddamn Bibles? Jesus was born when? In the middle of winter? Lot of Shepherds out watching their flocks around that time of year in Bethlehem? No, because they’d be freezing their fucking asses off. Tell you what – y’all go figure out which one of the different Bible stories about the birth of Baby Jesus® you want to believe, and then we’ll argue about whether it fucking happened like that or not.

Christians just stole a bunch of traditions from other cultures, slapped them together, stuck a fucking tinfoil star on top and called it the Most Important Holiday of the Year. Modern American Christmas makes Michael Jackson look positively organic.

But you boys at FOX still freak out every year about how everyone's out to get your special trees. This is really the most important thing you have to talk about? Whether Target says Happy Holidays or Merry Christmas? Here’s a brainstorm: there’s a fucking war on. Our soldiers are out there dying in an Islamic shithole Country while you guys do your 14th live feed of the day from WalMart to show us what good little consumers we are. What Would Jesus Do? He’d jump over that newsdesk and kick your ass for that shit. Are you sure you want to hang your journalism credentials on a story about what some guy calls a tree? They should break one of the branches off and shove it up his arse raw and with the splinters still intact.

Well we’ve fucking had it. You want to play bullshit games and scream about how God’s fucking judgment is gonna come raining down on us if we don't start watching our vocabulary? Go right the fuck ahead. But let me clue you in on something: fire and brimstone ain’t no deterrent for us. We’re not going to hell, assholes, we’re fucking in hell. We live with you.

And fuck Easter too, you fertility-rite-celebrating,
whiny, self-righteous, don't-know-the- history-
of-your-own-religion assholes.

Fuck off.

:)

That has been tried many times. Several rather expensive electronic organs have come out claiming to emulate a Hammond. So far the real enthusiasts do anything to get their hands on the real thing, knowing that there will come a day when the last one croaks. IIRC it was Paul Shaffer (the guy who makes the music at david Letterman's show) who spent the equivalent of a luxury car to have one restored.

Probably good enough for his measly 32 volts. I need to modify that
circuit to work on outputs of 90 volts and 6 volts.

Ok, I am not much of an expert on instruments or music in general. But a Hammond organ can fill a living room with a sound that, with the eyes closed, you'd think you are sitting in a cathedral. And lots of rock bands wouldn't use anything else. That is why a lot of Hammonds have been "sawed in halves" so they can be transported to the next gig. You could even buy split versions built into professional transport cases.

They have a Hammond B3 at my church, with the Leslie speaker. There
is another model Hammond in storage that needs a lot of work. Someone
had it on their screened in porch and the finish is ruined, but it still
plays.

People like the old Hammond organs like the B3 because the can't go
out of tune. The mechanical tone generator makes sure of that. They
only sound like a skating rink in, get this, A SKATING RINK!

Hello Michael,

> They have a Hammond B3 at my church, with the Leslie speaker. There
> is another model Hammond in storage that needs a lot of work. Someone
> had it on their screened in porch and the finish is ruined, but it still
> plays.
>

Just make sure that the oiling intervals are religiously kept. If the other one still plays be grateful for that. If it's the same model or nearly the same keep it. Even if the finish is beyond repair some day you might be really thankful to be able to scavenge its tone generator once the TG on the other Hammond goes.

A bad finish is often easy to fix compared to taking the whole machinery apart. Ours has a superb finish condition but it had been run dry for more than a decade before it was given to us. So the TG is quite worn :-(

Actually it was so bad that when I was done it gulped almost two cans of Hammond oil.

Some words of caution: The rectifier tube of the amp in the bottom is located pretty close to the back and it gets freaking hot. I would take care that the organ is never placed against a curtain or other flammable material and that nobody stores any stuff behind it. The power cord on ours almost crumbled in my hands and when attemting to swap it I discovered that this instrument did not have a single fuse. So I made a nice box with fuse and IEC connector.

Regards, Joerg

My kids school no longer has x-mas plays. They are not allowed to pray in school. In her religion class, they do not study any form of Christianity. Bill O'Reilly was cleared of the sex allegations,and if you would have kept up with that bit of the news, you would know that Bill O'Reilly's lowers WANTED them to release the alleged tapes because there were none. I could go on, but it would be a waste of bandwidth and your going to believe what you want no matter what I say.

Well, being the insufferabley pedantic researcher that I am, I came
up with a page:
http://en.wikipedia.org/wiki/Hammond_organ

that about a third of the way down, says:
"... Accurate imitation of the Hammond sound with simple electronic
circuitry was difficult, because the subtly-changing phase relationships
between tonewheels could not be easily replicated...."

OK, fair enough. :-)

I guess a piano is even harder - they don't even reproduce well from a
live recording! :-)

Cheers!
Rich

Even with complicated electronics it wasn't. IIRC it was Suzuki-Hammond
which came out with the XK2 and then the XK3. Those are pretty elaborate
synthesizer organs. But according to the experts it just ain't the same.

Buy a DC-DC converter that includes other protection features (ie overvoltage and overcurrent protection) and outputs known parameters (ie ripple voltage). I doubt you will find a single DC-DC converter for both voltages. But a small converter for each voltage should work. Many sources including this one that just arrived on my desk - www.astrodyne.com .

BTW, power from automotive systems should also worry about load dump. Technically load dump can be a transient as much as 270 volts on a 12 volt system. In reality, such events may only be 50 volts or less. Transients that would not damage other automotive electronics already designed for this rare and so destructive event.

That is a problem with some regulators such as 78xx series. Maximum voltage is typically not sufficient for automotive purposes - would require additional protection.

It seems like, no matter how closely you try to mimic the waveform of a
real instrument, there's always something that says, "This is electronic."
Or, maybe more accurately, "This is not real." ;-)

Cheers!
Rich

This is what transzorbs
http://www.vishay.com/docs/88301/15ke.pdf
and hash chokes are for.

I'm not affiliated with Vishay, formerly General Semiconductor,
just a satisfied customer. I've used them to protect circuits
against the transients caused by a 5 KV arc in an ion gun. :-)

Cheers!
Rich

I'm going to build a modified Lythall but I need to determine what the
wattage of the 330 Ohm resisters would be. I'm thinking they should be
fairly high.

Actually SGS Thompson that specifically makes protectors for
automobiles and load dump (do what 'too small' transzorb would
also do) acknowledge in their app notes that:
> " ... there are several existing products products able to
> clamp this overvoltage at the board level, for example the
> LDP24 or RBO series. The protection at the alternator level
> is a quite new concept and all the technical problems do not
> seem to be completely solved."

This would explain why an 'up to 270 volt' transient is not
routinely observed. Still, automotive electronics typically
should withstand about 50 volts ballpark without damage.
Transzorb could be but one part of that protection system. Or
a DC to DC converter that specifically has such protection
could be obtained. A weakness of Transzorbs are their low
power abilities. The advantage - those avalanche diodes can
handle so much more power than conventional zeners. My first
design that used Transzorb was maybe 20 years ago. GS was
selling Transzorbs even long before then.

Load dump does not occur frequently. But that one time can
be so destructive. Best to consider load dump when attaching
any electronics to automotive power because even trivial
protection does so much.

I have a feeling that this is exactly the problem. Engineers try to
mimic the output waveform instead of looking how the real instrument is
built. If they did that, they'd try to emulate all the individual parts
and pieces.

I heard a decently accurate electronic piano sound long before I heard anything remotely resembling the timber of a B3. Still haven't heard anything that sounds exactly like a B3 (other than an A100 or another B3).

In case of a Hammond organ it might since it has a speaker. Of course, it's a tube amp but that is a whole other matter which alone could make this thread balloon.

It'll take a lot of gyrators and filters but considering that one can buy a 400MHz DSP for less than a crate of beer these days it should be feasible. In case of our piano the DSP still couldn't win. The piano doesn't need power. Not even light since it has its own candles.

what kind of bearings? - ball bearings are like tubes - thay have
numbers and substitutes. Bronze bearings are routinely made by
machinists. Babbit is hardest as it is poured in place but you might
be better off replacing them with something else like bronze. Bearing
technology is not all that complicated if you poke into the right
group of folks.

That is a "Leslie" speaker. I have to service the one at my church.
The bearings are shot.

RG> Thanks!
RG> Rich

One wouldn't use gyrators and phase shifters but rather wavetables.
In a nutshell, it is a sample (digital recording) of the real
instrument. Then it is digitally manipulated to add modulation, timbre
characteristics, and whatever other effects are required for the
instrument. This is calculated for each note and stored in a table in
memory, hence the name wavetable. Then this is read out to the digital
to analog converter. The resulting sound is hard to tell apart from
the real instrument. Another even more realistic and versatile method
uses digital building blocks to mimic each physical component. For
example in the case of the human voice, the nose, the mouth, windpipe,
etc. One can create totally non-existant instruments like a violin
that sounds like a flute or whatever else you could possibly imagine.
There is a program which does this but I'm drawing a blank now.

That address works with the Scientific-Atlanta WebSTAR DPC2100 cable
modem, but only the "System" button is active, and it comes up as the
default.

>Is that galactic noise measured on a wide bandwidth antenna?
>What if it is very narrow band?

At 2 m the Sun is quite noisy, in addition the noise from the stars in
our Milky Way galaxy will contribute quite strongly to the background
noise levels with noise temperatures of several hundred Kelvins if the
antenna is pointing at the galactic plane.

However, if the antenna is pointing away from both the Sun and the
Milky Way, the noise levels are lower and thus, if you try to receive
a satellite in that direction, a low noise preamplifier will help. Of
course, this can be more easily observed on 70 cm and 23 cm, in which
the "cold sky" noise levels are even lower.

6422. What's it all about? - FAQ

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-29 13:03:11 UTC
From: Orator For Decency <aiyr.r.bean@lycos.co.uk>
Message-ID: <1135861391.024058.277720@o13g2000cwo.googlegroups.com>
Source record: 14955
Cross-posted to: uk.radio.amateur,rec.radio.amateur.policy,rec.radio.amateur.homebrew

In case there are those who got a CB-type rig such as the 817
in their stockings and were misled by
those-who-ought-to-have-known-better
into thinking that they were Radio Hams, the weekly
FAQ is posted a couple of days early to enable the parents to take
the CB gear back to the shop before the shops close for
another Bank Holiday.....

Please remember that this FAQ is a positive exhortation
to you to exert yourselves to join our fraternity! (If you find
otherwise, then perhaps you are already classing yourself in the
mediocre groups of those who are criticised in the FAQ and from
whom we _MUST_ dissociate? If so - it's never too late for
a re-taxonomisation on your part - there's nothing elitist about
us, and we welcome all those who are prepared to put themselves
out in order to join our ranks!)

-----ooooo-----

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are in a unique privileged position in that
they can construct and operate their own equipment! No-one
else has this privilege. Users, such as broadcasters,
the po lice and armed farces, CBers and mobile phone
users have to purchase ready-made gear. Manufacturers
are not licensed to operate their gear. Radio Hams
are qualified to design, build and then
operate their own pieces of equipment. They do this

with gusto, and also repair and modify their own
equipment. This is a privilege well worth the effort
to gain, and one to be jealously guarded.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

-----ooooo-----

One such CB type is the so-called "Not-Ham". Otherwise
known as the CBer-Masquerading-As-A-Radio-Ham, this type
had their background in the hobby that is CB Radio and not
in the technical pursuits that lead up to a coveted Ham licence.
Easily recognised by their boasts of the criminal activity of
11 metre SSB operation, one wonders why they don't go back to
the CB Bands if such bands are dearer in their hearts than are the Ham

Bands? No _REAL Radio Hams associate with those who made an
illegal installation of transmitting equipment before being
in possession of an appropriate licence.

-----ooooo-----

One infallible way to disambiguate the CB Radio Hobbyist
from the _REAL_ Radio Ham is to solicit their view of the
difference between CB Radio and Ham Radio. A Radio Ham will
perceive Ham Radio to be a technical pursuit and will
perceive CB Radio to be a social communications facility
no different in essence to a land-line telephone or a
GSM mobile in the hands of a 6-year-old. Thus a Radio Ham
could also hold a CB licence safe in the knowledge that
such a licence says no more about him than having a land-line
telephone, whilst continuing to regard Ham Radio as a separate
technical pursuit.

A CB Radio hobbyist, on the other hand, sees no difference between
a Ham Radio licence and a CB Radio licence. To him, they are
sisters-under-the-skin. Wrongly, the CB Radio Hobbyist then
tries to classify himself as the equal of the Radio
Ham when, in fact, he is nothing of the kind. A sure sign of
a CB Radio hobbyist is if he holds, or has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme.

-----ooooo-----

One group of people who claim to be of the standard of
Radio Hams but who are in reality nothing more than an
apology for the failure of a CBer are those class B
licensees who falsely proclaimed that they were against
the use of a Morse Test to control access to the HF
bands, until, that is, a test was introduced at their
intellectual level, the intellectual level of 6-year-olds.

6 year-olds simply lack the mathematical tool kit to
enable them to handle even the simplest algebraic manipulation
for Ohm's Law and thus, the disgraceful Class Ber's in
the aforementioned category are not Radio Hams by any stretch
of the imagination!

Remember - A sure sign of a CB Radio hobbyist is if he holds,
or has ever held, a licence issued under the gangrenous
degeneration that is the M3/CB Fools' Licence scheme!

It is to be noted that the OP also said, elsewhere, that "I wouldn't
recommend anyone whose background is in transistorised QRP
to tackle the neutralising of a compact PA stage with 600 VDC on the
anodes after replacing the antenna coupling capacitor ".

So, take warning that the so-called FAQ is not to be taken literally;
there are safety criteria that limit its generality. The author has
yet to publish these.

It is, for example quite unclear what the difference between a compact
PA with 600VDC on the anodes, and a non-compact PA that is otherwise
the same.

In that context, it is best ignored.

I noticed the reference in meow2's posting the question of budget workbenches. If anyone is interested, I have 2 references to simple, inexpensive workbench designs that I have used successfully. Both are made of plywood or similar material.

A small, but very useful one can be made from a 4'x4' (half sheet) of 3/4" plywood and provides a 24"x40" top. I built one of these for my wood shop using cheap plywood, though MDF would do. The second has a 28"x65" top and is cut from a full sheet. I used 3/4" MDF for this and it works great as a desk or as a work table.

As the designs are in published materials, I don't feel right posting them to a site or a NG. I would be willing to respond to an email at: -... -- -... ..- .-. . ... @ .-. --- --. . .-. ... .-.-. -.-. --- -- (If I'm posting to who I think I'm posting to, you won't have trouble figuring out my email id. If you can't. please don't flame me for being too clever, but ask and I will find a different way.

That was an accessory item, a Leslie speaker. A huge cabinet with a rotating speaker on slide contacts, motors, gears. We don't have one and we wouldn't know where to put it anyway. The amp under the organ is only 20W AFAIK with a huge speaker. That's real watts, not PMPS or whatever kids call "power" these days. Meaning it can make the sound of a large pipe organ and not lose steam after holding the bass chord for more than a hundred milliseconds.

>
> Sure, but can you flip a switch and be playing the flute or er-hu?
>

Actually you could. Ours doesn't have the flute presets but drawbars. With these you can set the ratio of all the harmonics and the manual shows the settings for a lot of common instruments. Some sound real, some don't. But we also have a small environmentally friendly (zero electric power, made from wood) flute. Not that I can play it but my wife can.

More like bronze bearings. But it ain't that easy. When you take it apart you end up with hundreds of pieces. It is the most complicated concoction of moving mechanical parts I ever encountered. The photo at near bottom show just a small part of it:

Mike -

That is a fairly standard IP address usage for DOCSIS 1.0/2.0 compliant
cable modems. The Linksys and Motorola modems also use these addresses as a
default.

You can look at the statistics on some of these modems, however the firmware
and configuration files for various cable modems are only uploaded from the
head-end of the cable system's equipment.

IF you have a router/gateway after the modem, these are usually 192.168.1.1

Newark has been placing their over stock items on eBay for the past few
months. Some interesting items for repair or homebrew construction
occasionally appear.

Today a Cellular Phone Service Kit with free shipping at $ 25 appeared
eBay Item number: 7576616984
This item use to sell for around $65

A few nice tools to have,
that are not always common on the workbench:

a.. 4 piece spanner screwdriver set:
a.. M1.7
b.. M2.0
c.. M2.3
d.. M2.6
a.. PRO-SOFT Duplex color nutdrivers and screwdrivers:
a.. Nut: 5 mm, 6 mm
b.. Torx: T5, T6, T8, T10
c.. Phillips: # 1 x 75 mm
d.. Slotted: 5 x 75 mm
gb

Thanks. They didn't have broadband internet on cable systems when I
worked in the business. I repaired headend and distribution equipment
back in the '80s.

Actually, I have a Linksys router and a Belkin Wireless G router on
my network. The Linksys is in the 192.168.1.X range, but the Belkin is
in the 192.168.2.X range. I have it set up this way because the DHCP
server in the Belkin is a severe bottleneck, dropping my bandwidth down
to barely more than dialup, but the Linksys gives me over 2 Mb per
second. I should have taken the Belkin crap back to Circuit City they
day that I bought it.

Jo> That was an accessory item, a Leslie speaker. A huge cabinet with a
Jo> rotating speaker on slide contacts, motors, gears.

Later on the speaker didn't rotate. The speaker was mounted face up.
Covering the speaker was a rotating funnel with 2 output horns at the
apex. The dual rotating horns gave a strong Doppler Effect that was
hard to duplicate electronically. A belt turned the rotating funnel
which was driven by a variable speed motor under user control.

With many thanks again to those on < rec.antiques ..... who previously identified possible sources.
But nothing yet!
So; still seeking one used knob for the Vol, RF gain or Bandswitch position of a circa 1955 Hallicrafter S-53A.
Knob is about one inch diameter and is serrated/ridged.
The smaller knobs on this model do 'not have' round aluminum inserts or the silver inner rings of some Hallicrafter style knobs.
I also have at least one of the slightly larger Hallicrafter style 'tuning/bandspread' knob; approx 1.5 inches diameter and which 'does have' the inner silver ring. Someone mentioned KF6AR in 2004 was seeking such a knob?
Also mentioned was that it may be possible to get a knob (or set of knobs) 'made', but they will 'look' different?
Best regards for the New Year.
Terry
PS. A few miles from where, in December 1901 Marconi received the first Transatlantic wireless telegraph signal at St. John's, Newfoundland (VO1xx country! Now part of Canada).

Hello all

I've been doing a fair bit of internet reading about RF construction projects. I'm still confused about something.

Most authors, including those in the ARRL Handbook, seem to espouse "ugly construction" and a variant called Manhatten construction. I understand that the reason is that these techniques minimize capacitance by providing a large ground plane. Ugly construction seems to also encompass perfboard construction with wire traces or direct component-to-component connections. This seems to me to be not much better than using pre-printed boards whose traces match, in geometry, those of solderless prototyping boards.

I do understand that the solderless boards are inadequate for RF work, but are the pre-printed perforated "protoboards" also inadequate.

Call it an OC tendency, but ugly construction is, well, ugly. Of course, I want to use the best techniques for what I'm doing, and if UC is the way to go, then that's what I'll do.

I'd appreciate your opinions on this.

Thanks
Basil B.

I think the primary reason that folks espouse ugly construction is that it may look bad to us, but the electrons like it just fine. It can be tough to get over the aesthetics (or lack thereof) of your fine new circuit, but it'll work just as well and it'll be less work than using a PC board.

You can, of course, make a PC board. Unless you know _exactly_ what you're doing you'll end up making mistakes, which will require changes, which you won't get right the first time. So if you have your new, flawed, PC board you'll modify it, and the mods will be, well, ugly.

So if you're going to make something ugly anyway, why not make it ugly to start? Once it works right then you can make a nice pretty PC if you feel like it.

>Well, that is certainly a vote for UC. Do you also have an opinion of
>the other idea, using pre-patterned, pre-etched boards such as
>Veroboard and the like?

My own feeling, for what it's worth, is that these are pretty good for DC and audio-frequency projects, but can have problems at RF.

A big part of the issue is one of grounding. Many of the pre-etched proto boards I've seen use most of their real estate for pads and pad-connection strips. There are usually sets of traces for supplying power and ground to the components, but these don't use more than a relatively small amount of the board's copper area and are often run as long strips coming in from the side of the board.

As a result, if you have two groups of components which are physically fairly close together, and connect components in these groups to the physically-closest ground pads/strips (minimizing the lead length), you may find that there are actually quite a few inches of PC-board ground trace between one component's "grounded" lead and another.

This is usually adequate at DC and audio frequency. At RF, the parasitic inductance of those long looping ground traces can have an adverse effect on the circuit's stability. You can sometimes minimize this by using a star-grounding approach, but since the connection pads are pre-etched into clusters and strips there's likely to be a limit to the number of components that you can connect to a "single point" ground, and it may not be all that good an approximation of a true single-point.

One of the recipes for making stable, friendly, and reproducible designs at RF seems to be to minimize the impact of parasitic reactances. As you point out, using "ugly" construction of the Manhattan or free-air (point-to-point) variety minimizes parasitic capacitance between components, and between components and the board.

It also has the benefit of minimizing parasitic _inductive_ reactance in the circuit's "ground", if you use a solid copper ground plane as the basis for your construction. "Ground" is always an approximation... a perfect ground cannot be achieved at either DC or RF... but you can get closer if you have lots of copper area to work with.

Etched PC boards can be used quite successfully for RF projects, of course, and often are. It's important, when laying out such a board, to minimize unwanted parasitics... leaving large sections of un-etched copper for grounding, using wide traces, paying attention to where the

actual ground currents flow, adding ground-shield traces between any
signal-carrying traces that might tend to suffer from cross-coupling,
and so forth.

One usually does not have the luxury of being able to take advantage
of these techniques (at least to their fullest) when using a
pre-etched proto board,

6451. Re: Ground Plane construction vs pre-printed "protoboards"

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-30 21:02:52 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <11rb8402jauvr7b@corp.supernews.com>
Source record: 14984

It's much easier to make a sensitive RF circuit work with "ugly" construction than on a typical PC board. There are a couple of reasons. One is that leads can generally be kept shorter. The second, and chief reason, is the solid, continuous ground plane. The advantage of the ground plane isn't capacitance reduction as you say, but much lower ground inductance. In a typical PC board layout, currents from various parts of a circuit have to flow through ground traces which can have considerable impedance at RF. This causes voltage drops which are related to each of the currents. The voltages are applied to the connected circuits, resulting in crosstalk and feedback.

It's usually possible to get by with a fairly abbreviated ground system, but it can take an awful lot of care and knowledge to do it -- I haven't even run across a lot of otherwise skilled engineers who are good at it. The average home constructor is much more likely to succeed on the solid plane provided by "ugly" construction. It's not uncommon for an "ugly" prototype to work well and a PC board version fail -- unless you have the luxury of using a multiple-layer PC board where you can devote one layer to being a solid ground plane. The chances of succeeding with a PC depends heavily, of course, on the nature of the circuit -- some are vastly more tolerant than others.

I personally like "ugly" construction also because it's much faster than making a PC board and, if done right, can be as rugged. Of course the advantages of a PC board are obvious when making multiple copies of a project.

I know of what I speak -- I've spent a career designing electronic test equipment, and do consulting in the EMC field (electromagnetic compatibility, dealing with such issues as crosstalk and RFI). And I've done a considerable amount of RF homebrewing.

Take a peek at the work of K8IQY who really made Manhattan construction
popular, or K7QO, who has some tutorials on the subject. Their work is
anything but ugly.

Mine on the other hand ...

6457. Identifying a mystery diode

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-12-31 00:05:28 UTC
From: Paul VK3DIP <pmcmahon@telstra.com>
Message-ID: <cXjtf.136133$V7.93540@news-server.bigpond.net.au>
Source record: 14990

Hi all I recently purchased a bag of unmarked supposedly diodes and I am
trying to figure out what they are. The clues so far are normal diode
action on a multimeter (ie conducts one way but not the other) but the
forward voltage is high at about 1.4 - 1.5 volts. The packaging is a small
square black plastic box with flat axial leads one of which has a small
cross
piece on it. This packaging suggests small signal or at least low power.

If anyone wants to look at the mystery diode it is the top one
in this picture.
http://www.users.bigpond.com/pmcmahon/mysterydiode.jpg
The bottom one is a normal glass 1N914 just for scale.

There is nowhere for the light to come out (or in) so they are not LEDs
which is the only other diode like component I have come across with that
high a forward voltage. Could it be two silicon diodes in series?

Any suggestions or even just identifying the case outline would be
appreciated.

Thanks
Paul VK3DIP

I've done carfully constructed dead bug (ugly) RF hardware that works
well at 2.4ghz and is not ugly It's a very effective techniques and
with modest care it's difficult to do better with etched circuits at
VHF or higher.

Some of my best radios and test gear have been built this way
and some test items are now several decades old. It can be very
rugged as well.

Sounds like the 1KV diodes RS used to sell. it was two lower voltage
silicon rectifiers in series. In your case the forward voltage is in
the right range for two silicon diodes in series.

==========
Ugly construction can in fact be very neat.
I normally use double sided PCB and drill holes to suit such that components to be grounded can be fitted perpendicular directly to the board without wire ends. These then also serve as support for non-grounded components. If non-grounded components are on their own I fit 10 MOhm resistors as 'practical stand-off insulators'. Where inductance is a critical element I use metal film resistors for this duty ,but normally carbon film resistors are fine.
All board mounted components are soldered to board on both sides such that both copper sides are bonded at various places.
Integrated circuit are glued 'dead bug style' with ample opportunity to connect other components.
For VHF and higher I line the board edges with folded very thin copper strip.
I am fortunate having found a roll with 6mm wide strip with a total length sufficient 'for life', at a flea market.

Ugly is definitely in the eye of the beholder. :) If it bugs you, then you might consider enclosing your modules in neat-looking Hammond boxes, connecting them with exotic gold-plated SMA/SMB/SMC hardware. When the lid is screwed down on the box, nobody can see the ugly stuff. I've built (almost) an entire receiver this way:

http://www.speakeasy.net/~jmiles1/ke5fx/equinox/equinox.html

Only the 1st LO synthesizer(s) are built on PC boards, and it wasn't strictly necessary even in those cases. The prototype LO was built ugly-style, and works just fine.

Perfboard can best be thought of as equivalent to conventional single-sided PC boards, with no ground plane. As Roy pointed out, you often don't care about stray capacitance as much as you care about having ubiquitous access to a low-inductance ground. You don't get that with either single-sided PC boards or perfboard.

Personally, I don't think much of the idea of fabbing a PC board for a one-off project, unless it involves newfangled chips with more pins than you can see. And perfboard, for me, is not the method of choice for anything but digital work -- although people have certainly used it to build some very nice gear.

If you want a technique that both looks good and is RF tolerant, try using double sided board and small pieces of cheap plastic insulation tape as resist. This applies to through hole parts of course - if you want to use SM you will have to use dead bug or professionally made PCBs. You will have to think out your layout carefully before you start - do this on paper. You can always go back and styart again if it is all wrong

The board must be scrupulously clean - use steel wool for this and dont touch with fingers afterwards.

You can do through hole ICs by cutting a matrix of tape from a single piece on the target board and removing the scrap from beween pads with fine forceps.

Cut small squares and strips of tape from sections laid out on another piece of scrap board for traces, resistors, capacitors and transistors. Cut the tape sections with a sharp blade such as a Stanley knife
Using fine forceps, lift these and place in your desired layout on the target board as pads and connections on the bottom side. Press down firmly with another tool to stick

Cover the top completely with tape as a ground plane.

Etch the board in Ferric Chloride.

Remove all the pieces of tape

Drill holes through the pads with a suitable size PCB drill from the bottom - a small drill press is useful as you will tend to break drills otherwise

Any pads connected to ground can be left so that the component lead can be simply soldered to the ground plane, while those that must be insulated are countersunk carefully on the top side to remove a small ring of copper - be careful not to drill right through - use a drill at slow revolutions, or even by hand in a T chuck.

Scrub again with steel wool and spray with PCB lacquer

With practice you can make quite complex boards - I did a complete triband HF SSB/QRP transceiver using this technique some years ago. I have used some SM components such as 1206 resistors and capacitors, combined with through hole parts on occasion.

Don't count it out as not being an LED. Some opaque-to-the-human-eye
packages are, in fact, quite clear in either the IR or UV range.
It could be an IR LED. (There's been many cases where light-sensitive,
'ordinary' diodes caused 'problems' in circuits on a well lit workbench.
The 'thing' would work one way in a buttoned-up case, and another way
under test.)

Other than being black, that thing looks suspiciously like an LED, so I
would go for an IR LED.

You could apply power it to as you would an LED (using a
current-limiting resistor), and take a look at it in a digital camera's
display. Digital cameras are somewhat sensitive to IR, even though they
usually have a built-in IR cut filter. Try it with an IR remote control
to see what I mean.
